Abstract

Background A syndrome of young-onset diabetes mellitus associated with microcephaly, epilepsy and intellectual disability caused by mutations in the tRNA methyltransferase 10 homologue A (TRMT10A) gene has recently been described.

Case report We report two siblings from the fourth family reported to have diabetes mellitus as a result of a TRMT10A mutation. A homozygous nonsense mutation p.Glu27Ter in TRMT10A was identified using targeted next-generation sequencing and confirmed by PCR/Sanger sequencing. Diabetes was diagnosed while the subjects were in their 20s and was characterized by insulin resistance. Epilepsy and intellectual disability were features in common. Mild microcephaly was present at birth but their final head circumferences were normal.

Conclusion Our report provides independent confirmation of the role of TRMT10A mutations in this syndrome and expands its phenotypic description. TRMT10A sequencing should be considered in children or adults with young-onset diabetes who have a history of intellectual disability, microcephaly and epilepsy. This report also shows the advantages of using a targeted panel to identify previously unsuspected monogenic diabetes among young-onset non-insulin-dependent diabetes in the absence of obesity and autoimmunity.

Introduction

Recently, a novel syndrome of young-onset diabetes mellitus or abnormal glucose homeostasis associated with microcephaly, epilepsy and intellectual disability attributable to homozygous mutations in the tRNA methyltransferase 10 homologue A (TRMT10A) gene was reported in two families [1,2]. In another report, an individual with TRMT10A deletion with failure to thrive, delayed puberty, intellectual disability and diabetes was described [3].

In the present paper, we report two siblings with young adult-onset diabetes, associated with intellectual disability, microcephaly in childhood and epilepsy, as a result of a third homozygous mutation in the TRMT10A gene.

Case report

The proband was the first child born to non-consanguineous white parents (Fig. 1). The pregnancy was uneventful and the child was born at term without postnatal problems. The child’s birth weight was 2700 g (-1.6 SD), length was 47.2 cm (-1.7 SD) and she had mild microcephaly [head circumference 32.5cm (-2 SD)]. She had mild intellectual disability, first noticed when she attended primary school, but other developmental milestones were normal. She was diagnosed with grand-mal epilepsy at 5 years old. MRI of the brain was normal. Her head circumference was 49 cm (-2SD) at 6 years 9 months old but improved to 50.3 cm (-1.3 SD) at 9 years 5 months old. Her final head circumference was normal at 53.1 cm (-1.3 SD). Growth in terms of height and weight was normal. Diabetes was diagnosed at 24 years old [plasma glucose 25.1 mmol/l, HbA1c 142 mmol/mol (15.1%), BMI 24.2 kg/m2 (weight 62.8 kg, height 1.61 m)]. She had a buffalo hump but features of familial partial lipodystrophy and Cushing’s syndrome were absent. She did not have ketoacidosis and was negative for antiglutamic
acid decarboxylase and anti-islet antigen-2 antibodies. She was treated with insulin (1.0–1.2 units/kg/day) and metformin. Her HbA1c ranged from 50 to 85 mmol/mol (6.7 to 9.9%). Fasting C-peptide, measured 8 years after diagnosis, was detectable at 540 pmol/l. She had severe preproliferative retinopathy at 4 months after diagnosis, suggestive of long-standing hyperglycaemia, but has no nephropathy or neuropathy to date.

The proband’s brother was born at 43 weeks gestation. Microcephaly was described at birth but the head circumference was not recorded. His birth weight was 3274 g (-0.7 SD). He started walking at 3 years old and could first speak in phrases at 6 years old. He attended special school because of intellectual disability. Epilepsy was diagnosed at 4 years old and he had delayed puberty. His final head circumference was normal at 54.5 cm (-0.4 SD). Diabetes was diagnosed when screened at 28 years using a 75-g oral glucose tolerance test (OGTT; plasma glucose 8.8 mmol/l at 0 min, 19.8 mmol/l at 120 min). His HbA1c level was 60 mmol/mol (7.6%) and his BMI was 28.4 kg/m² (weight 89.0 kg, height 1.77 m). Physical examination was normal. Fasting C-peptide level was 1000 pmol/l. The HbA1c level improved to 43 mmol/mol (6.1%) after 3 months of metformin therapy.

Neither the proband nor her brother had spontaneous hypoglycaemia. Both of them had mildly elevated LDL cholesterol and normal liver function tests. Skeletal surveys showed attenuated frontal skull vaults in both of them, in keeping with the history of microcephaly, but epiphyseal dysplasia was absent. Both their parents had normal heights, head circumferences and BMI, no epilepsy, intellectual disability, diabetes or prediabetes (normal OGTT results). Their maternal grandparents, now deceased, had Type 2 diabetes diagnosed after their 60s; their genotypes are not known.

All subjects provided written informed consent for blood sample collection and studies, as well as for the writing and publication of this report. The proband had participated in the UNITED (Using Pharmacogenetics to Improve Treatment in Early-Onset Diabetes) study when analysis of her HNF1A and HNF4A genes did not identify any mutation. Testing for mutations in all of the known or putative monogenic diabetes genes as part of the study was undertaken using targeted next-generation sequencing as previously described [4]. Sequencing was performed with a HiSeq2000 system (Illumina, San Diego, CA, USA; 48 samples per lane) and 100 bp paired end reads. Mutation confirmation was performed by PCR/Sanger sequencing. Subsequently, samples of the proband’s brother and parents were tested for TRMT10A mutation using PCR/Sanger sequencing. Plasma glucose and insulin was measured in the proband’s brother and parents at 0, 30, 60, 90 and 120 min in the 75-g OGTT. As a comparator, surrogate indices for insulin resistance and β-cell function of the brother were compared with the means of four age- and BMI-matched healthy control subjects.

Results

Metabolic studies

The OGTT results of the proband’s brother are shown in Fig. 2. He was newly diagnosed with diabetes. The findings were suggestive of insulin resistance [Matsuda index 1.46;
homeostatic model assessment of insulin sensitivity (HOMA\%S) 34.7\%(5–7) and impaired β-cell function (insulinogenic index 0.21; disposition index 0.32; homeostatic model assessment of β-cell function (HOMA%β) 63.6\%(6–8). For comparison, the mean (SD) values for the four age- and BMI-matched controls were: Matsuda index 14.2 (9.5); HOMA% S 165 (114); insulinogenic index 0.99 (0.52); disposition index 12.70 (11.85); HOMA%β 106 (51). The Matsuda indices of the father and mother were 8.86 and 10.49, respectively.

Genetic studies

A homozygous G to T transition in exon 2 of gene TRMT10A at nucleotide position 79 of the coding sequence was identified in the proband. This variant replaces a glutamic acid residue with a premature termination codon at position 27 of the polypeptide (NM_001134665.1: c.79G>T; p.Glu27Ter). Mutations of other monogenic diabetes genes were not detected. This mutation was confirmed by Sanger sequencing to be homozygous in the proband and her brother, and heterozygous in both parents.

Discussion

Igoillo-Esteve et al. [1] first described a new syndrome of young-onset diabetes, microcephaly, intellectual disability and epilepsy attributable to a homozygous nonsense mutation p.Arg127Ter in TRMT10A in a consanguineous family of Moroccan origin, with three out of nine children affected. Gillis et al. [2] identified a missense mutation p.Gly206Arg in TRMT10A in three out of 12 siblings born to non-consanguineous parents from a small, inbred Jewish community in Uzbekistan. More recently, Zung et al. [3] described an individual with TRMT10A deletion with failure to thrive, delayed puberty, intellectual disability and diabetes. In the present paper, we report the eighth and ninth individual from the fourth family known to have this syndrome as a result of a TRMT10A mutation.

The clinical characteristics of our patients are compared with previous reports in Table 1. Diabetes caused by TRMT10A mutations was diagnosed between the ages of 9 and 28 years; two siblings did not have diabetes at the age of 13 and 14 years old. Interestingly, all three siblings in the family described by Gillis et al. [2] had hypoglycaemia, as did the individual reported by Zung et al. [3]; however, no hypoglycaemia was reported in our patients or in those reported by Igoillo-Esteve et al. [1]. The individuals in the report by Gillis et al. and in our family did not have high birth weight, suggesting intrauterine hyperinsulinaemia was not present. Insulin resistance appeared to be the dominant pathophysiological mechanism in our patients. This was shown by the OGTT results in our proband’s brother which were similar to those of the first individual described by Gillis et al. Similarly to the individuals reported by Igoillo-Esteve et al., the insulin requirement of our proband was quite high. Based on the OGTT results, the parents who had heterozygous mutation did not appear to be at increased risk of diabetes.

Microcephaly was a feature in common to all the reported cases, but the degree of severity appeared to vary. Microcephaly is defined as an occipito-frontal head circumference of >2 SD or >3 SD below the mean for age and sex [9,10]. Similar to those reported by Gillis et al. [2], our patients just met the criteria for mild microcephaly at birth; however, their head circumferences normalized as they grew and achieved normal final head circumferences. This was in contrast to the more marked microcephaly, which persisted to adulthood in the individuals reported by Igoillo-Esteve et al. [1] and Zung et al. [3]. All the individuals had intellectual disability, and epilepsy was common except in the individual reported by Zung et al. Contrary to the previous reports, our patients did not have short stature, although the proband did have a buffalo hump, as described in one patient previously [1].

A homozygous nonsense mutation, p.Glu27Ter, in the TRMT10A gene was identified in our patients. Data from the Exome Aggregation Consortium (ExAC) browser showed that the frequency of heterozygous TRMT10A nonsense mutations is ~1 in 4000, and the p.Glu27Ter mutation found in our family is the most common [11]. The family is unaware of any close common ancestor. In humans, TRMT10A is the orthologue most closely related to yeast TRM10, a protein that has tRNA m1G9 methyltransferase activity [12]. This nonsense mutation in TRMT10A at this location is likely to result in nonsense-mediated decay and reduced protein expression [13]. Reduced TRMT10A

NR, not reported. Mutations described in accordance with Human Genome Variation Society (HGVS) guidelines with the A of the ATG initiation codon numbered nucleotide c.1, using reference sequence NM_001134665.1 for TRMT10A.
mRNA expression and TRMT10A protein deficiency was previously shown to be the result of a p.Arg127Ter nonsense mutation [1]. TRMT10A protein is ubiquitously present but more abundant in human brain and pancreatic islets (diabetes) in our patients. The robust insulin secretion in our case supported the in vitro findings that TRMT10A silencing did not appear to affect β-cell function but may induce β-cell apoptosis [1]. The mechanism by which the mutation is associated with insulin resistance remains to be investigated.

In summary, the present case report provides independent confirmation of the role of TRMT10A mutations in this newly described syndromic form of monogenic diabetes and expands its phenotypic description. It also highlights the advantages of using a targeted panel to identify previously unsuspected monogenic diabetes in young-onset non insulin-dependent diabetes in the absence of obesity and autoimmunity. Children or adults with young-onset diabetes who have intellectual disability, microcephaly and epilepsy should undergo genetic testing for TRMT10A mutations. Further studies are needed to evaluate the prevalence of TRMT10A mutations in this phenotypic group.

**Funding sources**

This work was undertaken as part of the UNITED study, funded by the Health Innovation Challenge Fund (HICF), a parallel funding partnership between the Wellcome Trust and the Department of Health (grant no. 091985/HICF 1009-041). T.W.Y. is supported by an Academic Medicine Development Award from National University Health System, Singapore. S.E. is a Wellcome Trust Senior Investigator.
