ABSTRACT

Background

Treatment of cancer is increasingly effective but is associated with short and long term side effects. Oral and gastrointestinal side effects, including oral candidiasis, remain a major source of illness despite the use of a variety of agents to treat them.

Objectives

To assess the effectiveness of interventions for the treatment of oral candidiasis for patients with cancer receiving chemotherapy or radiotherapy or both.

Search methods

Computerised searches of Cochrane Oral Health Group and PaPaS Trials Registers (to 1 June 2010), CENTRAL via the Cochrane Library (Issue 2, 2010, 1 June 2010), MEDLINE via OVID (1 June 2010), EMBASE via OVID (1 June 2010), CINAHL via EBSCO (1 June 2010), CANCERLIT via PubMed (1 June 2010), OpenSIGLE (1 June 2010) and LILACS via Virtual Health Library (1 June 2010) were undertaken.

Reference lists from relevant articles were searched and the authors of eligible trials were contacted to identify trials and obtain additional information.

Selection criteria

All randomised controlled trials comparing agents prescribed to treat oral candidiasis in people receiving chemotherapy or radiotherapy for cancer. The outcomes were eradication of oral candidiasis, dysphagia, systemic infection, amount of analgesia, length of hospitalisation, cost and patient quality of life.

Data collection and analysis

Data were independently extracted, in duplicate, by two review authors. Trial authors were contacted for details of randomisation and withdrawals and a quality assessment was carried out. Risk ratios (RR) were calculated using fixed-effect models.
Main results

Ten trials involving 940 patients, satisfied the inclusion criteria and are included in this review. Drugs absorbed from the gastrointestinal (GI) tract were beneficial in eradication of oral candidiasis compared with drugs not absorbed from the GI tract (three trials: RR = 1.29, 95% confidence interval (CI) 1.09 to 1.52), however there was significant heterogeneity. A drug absorbed from the GI tract, ketoconazole, was more beneficial than placebo in eradicating oral candidiasis (one trial: RR = 3.61, 95% CI 1.47 to 8.88). Clotrimazole, at a higher dose of 50 mg was more effective than a lower 10 mg dose in eradicating oral candidiasis, when assessed mycologically (one trial: RR = 2.00, 95% CI 1.11 to 3.60). Only one of the ten trials was assessed as at low risk of bias.

Authors’ conclusions

There is insufficient evidence to claim or refute a benefit for any antifungal agent in treating candidiasis. Further well designed, placebo-controlled trials assessing the effectiveness of old and new interventions for treating oral candidiasis are needed. Clinicians need to make a decision on whether to prevent or treat oral candidiasis in patients receiving treatment for cancer.

Plain Language Summary

Interventions for treating oral candidiasis for patients with cancer receiving treatment

Cancer treatment can lead to severe fungal infections (candidiasis, called thrush) in the mouth. This can cause pain, difficulties in eating and longer hospital stays. Infection can sometimes spread through the body and become life-threatening. Different drugs are used to try and relieve candidiasis. There is insufficient evidence that any of the antifungal drugs may cure fungal infections in the mouth for people with cancer and more research is needed.

Background

Treatment of solid malignant tumours and the leukemias with cytotoxic chemotherapy or radiotherapy or both is becoming increasingly more effective but it is associated with short and long term side effects. Among the clinically important acute side effects is the disruption in the function and integrity of the oral mucosa. The consequences of this include severe ulceration (mucositis) and fungal infection of the mouth (oral candidiasis). These disease and treatment induced complications may also produce oral discomfort and pain, poor nutrition, delays in drug administration, increased hospital stays and costs and in some patients life threatening infection (septicaemia).

Patients with cancer are advised to maintain oral hygiene. Depending on the cancer centre, the patient’s age and the expected toxicity of their treatment protocol, additional agents may be provided to prevent oral complications. Nevertheless, oral complications remain a major source of illness despite the use of a variety of agents to prevent them. A recent Cochrane review looked at the use of oral and topical prophylactic agents for the prevention of oral candidiasis in patients with cancer treated by chemotherapy (Clarkson 2007a). The review concluded that there is strong evidence, from randomised controlled trials, that drugs absorbed or partially absorbed from the gastrointestinal (GI) tract prevent oral candidiasis in patients receiving treatment for cancer. There is also evidence that these drugs are significantly better at preventing oral candidiasis than drugs not absorbed from the GI tract. This present review follows on from this and looks at the treatment of overt oral candidiasis in patients receiving treatment for cancer. This review is one in a series of four Cochrane reviews looking at the prevention and treatment of both oral candidiasis and oral mucositis (Clarkson 2007a; Clarkson 2007b; Worthington 2007).

Objectives

To assess the effectiveness of interventions (which may include placebo or no treatment) for the treatment of oral candidiasis for patients with cancer, receiving chemotherapy or radiotherapy or both.

The following primary null hypothesis was tested for comparisons between groups treated for oral candidiasis:

There is no difference in the proportion of patients without oral candidiasis after treatment.

The primary outcomes were therefore:
• Eradication of candidiasis
• Improvement of candidiasis.

In this review we proposed to address the hypothesis of no difference between groups treated for oral candidiasis for the following secondary outcomes if data were available from studies which included a primary outcome:

• Relief of pain
• Amount of analgesia
• Relief of dysphagia
• Incidence of systemic infection
• Days stay in hospital
• Cost of oral care
• Patient quality of life.

The following subgroup analyses were proposed:

• Cancer type (leukaemia, solid cancer and mixed)
• Cancer treatment type
• Age group (children, adults, children and adults).

METHODOLOGY

Criteria for considering studies for this review

Types of studies
Only randomised controlled trials were eligible for inclusion in this review.

Types of participants
Anyone with cancer who received chemotherapy or radiotherapy or both and had overt oral candidiasis.

Types of interventions
Active agents: any antifungal intervention for the treatment of oral candidiasis.
Control: may be placebo or no treatment, or another active intervention.

Types of outcome measures

Primary outcome:
• Oral candidiasis (absent or present)

Secondary outcomes:
• Relief of pain
• Amount of analgesia
• Relief of dysphagia
• Incidence of systemic infection
• Days stay in hospital
• Cost of oral care
• Patient quality of life.

Search methods for identification of studies

This review is part of a series of four reviews on the prevention and treatment of oral candidiasis and oral mucositis in patients with cancer, and the same search strategies were used for all four reviews.
The searches attempted to identify all relevant trials irrespective of language. Papers not in English were translated by members of The Cochrane Collaboration.

Electronic searches:
The following databases were searched:
- Cochrane Oral Health Group Trials Register (whole database, to 1 June 2010) (see Appendix 1)
- Cochrane Pain, Palliative and Supportive Care (PaPaS) Group Trials Register (whole database, to 1 June 2010) (see Appendix 1)
- Cochrane Central Register of Controlled Trials (CENTRAL) (The Cochrane Library 2010, Issue 2; searches conducted 1 June 2010) (see Appendix 2)
- MEDLINE via OVID (1950 to 1 June 2010) (see Appendix 3)
- EMBASE via OVID (1980 to 1 June 2010) (see Appendix 4)
- CINAHL via EBSCO (1980 to 1 June 2010) (see Appendix 5)
- CANCERLIT via PubMed (1950 to 1 June 2010) (see Appendix 6)
- OpenSIGLE (1980 to 1 June 2010) (see Appendix 7)
- LILACS via the Virtual Health Library (1980 to 1 June 2010) (see Appendix 8)

Sensitive search strategies were developed for each database using a combination of free text and MeSH terms. The MEDLINE and CANCERLIT subject searches were conducted with the addition of the Cochrane Highly Sensitive Search Strategy (CHSSS) for identifying randomized trials in MEDLINE: sensitivity maximizing version (2009 revision) as referenced in Chapter 6.4.11.1 and detailed in boxes 6.4.a and 6.4.c of the Cochrane Handbook for Systematic Reviews of Interventions Version 5.0.2 (Higgins 2009).
Filters developed by the Cochrane Oral Health Group for identifying randomised controlled trials were used for the searches of EMBASE and CINAHL. The LILACS subject search was linked to the Brazilian Cochrane Center search strategy for identifying randomised controlled trials in LILACS.

**Searching other resources:**

Only handsearching carried out by The Cochrane Collaboration is included in the search (see master list www.cochrane.org). The controlled trials database (www.controlled-trials.com) was also searched to identify ongoing and completed trials and to contact trialists for further information about these trials. The reference list of related review articles and all articles obtained were checked for further trials. Authors of trial reports and specialists in the field known to the review authors were written to concerning further published and unpublished trials. The review will be updated every 2 years using the Cochrane Oral Health Group Trials Register, CENTRAL, MEDLINE, EMBASE, CINAHL, CANCERLIT and LILACS. OpenSIGLE is no longer being updated and will not be searched for future updates of this review.

**Data collection and analysis**

**Selection of studies**

The titles and abstracts (when available) of all reports identified through the searches were scanned by two review authors (Jan Clarkson (JC) and Helen Worthington (HW)). Full reports were obtained for trials appearing to meet the inclusion criteria or for which there was insufficient information in the title and abstract to make a clear decision. The full reports obtained from all the electronic and other methods of searching were assessed independently, in duplicate, by two review authors to establish whether the trials met the inclusion criteria or not. Disagreements were resolved by discussion.

**Data extraction and management**

Data were extracted by two review authors independently using specially designed data extraction forms. The characteristics of the trial participants, interventions and outcomes for the included trials are presented in the study tables. Candidiasis was recorded as absent or present, and data for both clinical and mycological assessments were extracted. The duration of trials was recorded along with interim assessments and a decision made about which to use to maximise commonality. We also recorded the country where the trial was conducted, which year it was conducted and whether a dentist was involved in the investigation. Trial authors were contacted for clarification or for further information.

**Assessment of risk of bias in included studies**

The assessment of risk of bias for included trials was undertaken independently and in duplicate by two review authors. Studies were analysed for the following to assess validity as a threshold for inclusion of the studies, which is described as one of the options in the Cochrane Handbook for Systematic Reviews of Interventions Version 5.0.2 (Higgins 2009) on the following individual quality criteria:

- Adequate sequence generation: Yes, No, Unclear
- Allocation concealment: Yes, No, Unclear
- Blinding of participants and carers: Yes, No, Unclear
- Blinding of outcome assessors: Yes, No, Unclear
- Incomplete outcome data addressed: Yes, No, Unclear
- Free of selective outcome reporting: Yes, No, Unclear
- Free of other biases: Yes, No, Unclear

'Yes' indicates a low risk of bias, 'No' indicates high risk of bias and 'Unclear' indicates either lack of information or uncertainty over the potential for bias. A risk of bias table was completed for each included study. Results are presented graphically by study (see Figure 1) and by domain over all studies (Figure 2).
Figure 1. Methodological quality summary: review authors' judgements about each methodological quality item for each included study.

Risk of bias was assessed for each study. Studies were considered to be at low risk of bias if there was adequate concealment of allocation, blinded outcome assessment and information on the reason for withdrawal provided by trial group. If one of these criteria was not met a study would be considered at moderate risk of bias, otherwise at high risk of bias.

**Measure of treatment effect**

For dichotomous outcomes, the estimates of effect of an intervention were expressed as risk ratios together with 95% confidence intervals. For continuous outcomes mean differences together with 95% confidence intervals were used.

**Dealing with missing data**

Intention-to-treat analysis was to be conducted where possible. Methods outlined in the handbook (Higgins 2009) were used to impute missing standard deviations if these could not be obtained from trial authors.

**Assessment of heterogeneity**

We planned to investigate clinical heterogeneity by examining the different cancer types and age groups, however there were insufficient trials looking at the same intervention to undertake this.

**Assessment of reporting biases**

We tabulated all the outcomes considered here.

**Data synthesis**

Meta-analyses were done only with studies of similar comparisons. Risk ratios were combined for dichotomous data using random-effects models (fixed-effect models used if less than 3 studies in meta-analysis).

**Subgroup analysis and investigation of heterogeneity**

It was planned to undertake a sensitivity analysis to examine the effect of concealed allocation and blind outcome assessment on the overall estimates of effect. However there were insufficient trials to undertake this.

We proposed a priori to conduct subgroup analyses for different cancer types (solid, leukaemia and mixed), different types of cancer
treatment (chemotherapy, radiotherapy) and age groups (children, adults and mixed). There were insufficient trials by intervention type to undertake this.

The significance of any discrepancies in the estimates of the treatment effects from the different trials was assessed by means of Cochran's test for heterogeneity and quantified by $I^2$ statistics.

**RESULTS**

**Description of studies**

See: Characteristics of included studies; Characteristics of excluded studies.

**Results of the search**

The search was conducted for the four similar reviews in this series (Clarkson 2007a; Clarkson 2007b; Worthington 2007) and has now been repeated seven times since 1999 for different updates. The most recent searches in October 2008, August 2009, January 2010 and June 2010 identified 1924, 621, 394 and 294 records respectively. Following screening of all three databases 125 potential trials were identified for the four reviews. There was only one further trial to be included in this review update (Bensadoun 2008) and one further study to be excluded (Yamaguchi 2006).

**Included studies**

See Characteristics of included studies table for further details. One included study included episodes (n = 60) rather than patients (n = 56), but as these numbers were similar we decided to include the study.

**Setting**

Of the 10 included trials, four were conducted in USA (Flynn 1995; Hughes 1983; Shechtman 1984; Yap 1979) and six in Europe (Bensadoun 2008; Finlay 1996; Meunier 1990a; Meunier 1990b; Oude 2004; Studena 1995). Six of the trials received external funding, three obtained government funding and five acknowledged assistance from the pharmaceutical industry. The providers and assessors of the treatments were mainly medical staff although one of the trials involved a dentist (Finlay 1996). None of the trials involved the patients in the outcome measurement.

**Participants**

The results of the 10 trials included in the review are based on 940 patients. The range of patients was from 6 to 141 per treatment or control group.

Six of the 10 trials recruited only adult patients with cancer, one included both adults and children (Hughes 1983), one included only children (Flynn 1995) and in two trials the age of the patients was unclear (Meunier 1990b; Shechtman 1984). The type of cancer being treated was a combination of leukemias and solid tumours in seven trials (Flynn 1995; Hughes 1983; Meunier 1990a; Meunier 1990b; Oude 2004; Shechtman 1984; Studena 1995), head and neck cancer in two trials (Bensadoun 2008; Finlay 1996), and children with unspecified malignancies in the remaining trial (Flynn 1995). Little information was provided on the cancer treatment regimens received by patients in the trials. In one trial only radiotherapy was used (Finlay 1996), one trial used both cytotoxic chemotherapy and radiotherapy (Oude 2004) and for one trial information was provided for individual patients regarding the use of steroids and antibiotics in addition to chemotherapy (Shechtman 1984). The diagnosis of oral candidiasis at entry into the trial was usually a combination of both clinical and mycological diagnosis. However in two trials only clinical diagnosis was used (Finlay 1996; Studena 1995).

**Interventions**

All of the 10 trials provided a clear description of the interventions including the dose and method of administration for both the test and control groups. In only two trials was a comparison made with a placebo (Hughes 1983; Shechtman 1984). The majority of trials (six) compared different test agents with varying doses, frequency and duration of use. Two trials compared different doses of a test agent used at the same frequency and duration (Bensadoun 2008; Yap 1979).

The interventions for the 10 trials assessing the treatment of oral candidiasis were categorised according to the degree of absorption from the gastrointestinal (GI) tract.

Absorbed from the GI tract:
- fluconazole (Finlay 1996; Flynn 1995; Meunier 1990a; Oude 2004; Studena 1995)
- ketoconazole (Hughes 1983; Meunier 1990a; Meunier 1990b)
- itraconazole (Oude 2004; Studena 1995).

Partially absorbed from the GI tract:
- clotrimazole (Shechtman 1984; Yap 1979).
- miconazole (Bensadoun 2008)

Not absorbed from the GI tract:
- amphotericin B (Finlay 1996)
- nystatin (Flynn 1995; Meunier 1990b).

**Outcomes**

There was variation between the trials in the assessment of oral candidiasis. All trials reported both a clinical and microbiological outcome of oral candidiasis. All trials used the dichotomous...
clinical outcome ‘eradicated’ versus ‘not eradicated’. In addition two trials (Finlay 1996; Flynn 1995) compared the severity before and after treatment using a 4-point scoring system. For three trials (Meunier 1990b; Studena 1995; Yap 1979) the method of assessment was not given. Mycological assessments were based on cultures rather than smears in all trials and the dichotomous classification of eradicated or not could be obtained from all the 10 trials. Only in three trials were outcome measures of pain or dysphagia collected (Bensadoun 2008; Flynn 1995; Shechtman 1984) and only three reported side effects (Bensadoun 2008; Flynn 1995; Oude 2004).

Excluded Studies
See Characteristics of excluded studies table for further details. Seventeen of the apparently eligible studies were excluded: four were not randomised controlled trials (Holst 1984; Jorgensen 2006; Urabe 1990; Walsh 2002); nine did not have just oral candidiasis for entry into the study (Anaissie 1996; Benhamou 1991; Bourhis 2004; Fleming 2001; Lake 1996; Lefebvre 2002; Subira 2004; Verweij 1994; Walsh 2004); in one study the data were presented in terms of episodes not patients (Kostiala 1982); two trials were excluded as the data were not presented in an accessible form (Conrad 1990; Domenge 1999); and one study conducted in Japan included patients who were not receiving treatment for cancer (Yamaguchi 2006).

Risk of bias in included studies
The kappa score between the two raters was one for each item assessed. Letters were sent to authors of the trials and only one replied (Finlay 1996), the information supplied changed the concealment of randomisation from unclear to adequate, and clarified the withdrawals. One study was assessed as at low risk of bias (Meunier 1990a). The risk of bias assessment is summarised overall and for each trial in Figure 1 and Figure 2.

Adequate sequence generation
Adequate sequence generation was observed in four trials (40%), where a clear statement of the method of randomisation was reported. In the remainder of trials a judgment of ‘unclear’ was given as reporting lacked description with such statements as ‘were randomised’ or ‘were stratified’ appearing most commonly.

Allocation
Adequate allocation concealment was observed in the same four trials as above (40%). The remainder failed to indicate whether the generated randomisation sequence was concealed from individuals involved in the enrolment and assignment of participants.

Blinding
In four trials (40%) participants and carers were blinded to the allocated intervention. This was not done for the remaining six trials. Blinding of outcome assessors was adequate for five trials (50%), four being unclear and one not blinded.

Incomplete outcome data
In six trials (60%), incomplete outcome data was assessed as adequate. In the remaining four trials it was unclear which group the patients who were excluded for specific reasons belonged to.

Selective reporting
We consider all trials to be free of selective reporting as the primary outcomes were included in all.

Other potential sources of bias
This was unclear in eight trials and assessed as ‘no’ in two (Flynn 1995; Yap 1979) due to there being a unit of analysis problem with episodes rather than patients being used for the analysis. As the number of episodes was similar to the number of patients in both (60 and 56 in Flynn 1995; 186 and 180 in Yap 1979), episodes were used in the data analysis.

Effects of interventions

Comparison 1, Outcome 1.1 - Clinical: eradication of oral candidiasis
One of the two placebo controlled trials found a significant benefit (risk ratio (RR) = 3.61, 95% confidence interval (CI) 1.47 to 8.88) for patients taking the absorbed drug ketoconazole (Hughes 1983). In the other placebo controlled trial on the partially absorbed drug clotrimazole, no benefit was demonstrated (Shechtman 1984). Three trials compared different types of absorbed drugs with each other and they failed to demonstrate a benefit of one drug against another: one trial compared fluconazole with ketoconazole (Meunier 1990a); two trials fluconazole versus itraconazole (Oude 2004; Studena 1995). Three trials compared absorbed drugs (ketoconazole or flucona- zole) with drugs not absorbed (nystatin or amphotericin B). Two of these trials demonstrated a significant clinical benefit of the absorbed drug fluconazole over the non-absorbed drug nystatin (Finlay 1996; Flynn 1995), and the meta analysis found a benefit for the absorbed drugs over the non-absorbed drugs (RR = 1.29, 95% CI fixed 1.09 to 1.52; Chi² for heterogeneity P = 0.01). However there was substantial heterogeneity between the three trials with I² = 78%.
Comparison 1, Outcome 1.2 - Mycological: eradication of oral candidiasis

There were some differences between the results for the mycological assessments compared with those from the clinical assessment. Despite a significant clinical improvement there was no statistically significant difference in mycological eradication between an absorbed drug ketoconazole and placebo (Hughes 1983). However, there was evidence of different eradication rates with different absorbed drugs and a statistically significant benefit was found for fluconazole over itraconazole (RR = 1.17, 95% CI 1.04 to 1.33; Chi² for heterogeneity P = 0.30). In agreement with the clinical assessment there was a statistically significant difference in terms of a benefit for absorbed drugs compared to not absorbed drugs (RR = 1.82, 95% CI 1.28 to 2.57; Chi² for heterogeneity P = 0.001). One further trial (Yap 1979) demonstrated that 50 mg of the partially absorbed drug clotrimazole eradicated more cases than the lower dose of 10 mg (RR = 2.00, 95% CI 1.11 to 3.60). None of the studies reported: relief of pain, relief of dysphagia, incidence of systemic infection, amount of analgesia, days stay in hospital, cost of oral care, patient quality of life.

DISCUSSION

Whilst we have been able to achieve our objective in evaluating the effectiveness of interventions to treat oral candidiasis, there were insufficient trials to make strong recommendations for patient care. The generalisability of the results is difficult to comment on as reporting of the types of cancer and details of treatment was unclear and few trials included children. There were only two trials that compared the treatment of candidiasis using an active drug with a placebo. There was some evidence, based on one trial, that ketoconazole is effective, but there is a need for more trials that include a placebo group. The risk of hepatotoxicity with prolonged use of ketoconazole could influence treatment decisions and the UK Committee on Safety of Medicines has recommended that prescribers should weigh up the potential benefits against the risk of liver damage, and should carefully monitor patients both clinically and biochemically (BNF 2009).

There is evidence that absorbed drugs are more effective than drugs not absorbed from the gastrointestinal tract. There was no difference found in either trial comparing two absorbed drugs, and there was an indication that a higher dose of clotrimazole was more effective than a lower dose, although this was only found for the mycological assessment. There were no trials comparing partially absorbed drugs with either absorbed drugs or drugs not absorbed.

The findings from this review are disappointing as there were only 10 trials including 940 patients, 69 of whom were included in the two trials with placebo control groups. This is far fewer than the 28 trials with 4226 patients included in the prevention review (Clarkson 2007a).

There was limited consistency between trials on the clinical diagnosis of oral candidiasis and there was also little reported in terms of relief of pain, relief of dysphagia, incidence of systemic infection, amount of analgesia, days stay in hospital, cost of oral care and patient quality of life. It is therefore difficult to comment on the importance of these patient based outcomes, although they are frequently cited as the justification for conducting trials.

It is not possible to assess whether there was any evidence of publication bias however, with few trials and patients, this could be a major problem.

For patients being treated for cancer the clinical dilemma is whether to prevent or treat oral candidiasis. The findings from the prevention review would suggest that if the incidence of oral candidiasis for a patient subgroup is likely to be high then a drug absorbed or partially absorbed from the gastrointestinal tract should be prescribed at the start of cancer treatment. The incidence of oral candidiasis is variable and depends on the nature of the underlying disease and the intensity of treatment. For absorbed drugs in populations with an incidence of 20% (mid range of results in control groups), the number needed to treat (NNT) to prevent one extra case of oral candidiasis was 9 (95% confidence interval 7 to 13) (Clarkson 2007a).

The findings of this review should be considered in the context of the general medical management of patients with cancer. A review investigating the routine use of antifungal therapy in cancer patients did not find an effect on mortality and only a modest effect on systemic fungal invasion (Gotzsche 2002). The authors questioned the current widespread practice of prophylactic antifungal therapy and this finding should be considered when interpreting the results of this review where we are specifically looking at oral outcomes.

AUTHORS’ CONCLUSIONS

Implications for practice

Clinicians need to make a decision on whether to prevent or treat oral candidiasis in patients receiving treatment for cancer. The evidence on which drug should be prescribed is weak and unreliable.
Implications for research

There is a need for more well designed trials that compare the effectiveness of drugs absorbed, partially absorbed or not absorbed from the gastrointestinal tract with a placebo control. These should be conducted before comparing specific agents with each other. The limited evidence of effectiveness of current therapies, combined with side-effects profiles of those agents with proven efficacy suggest that new interventions for treating oral candidiasis are needed.

Acknowledgements

Thanks go to Anne Littlewood, Trials Search Co-ordinator for the Cochrane Oral Health Group for carrying out the searches for the review, Luisa Fernandez Maulefinch (Managing Editor) and Phil Riley (Assistant Managing Editor) for their help with the administration of the review which included sending out letters to authors and in locating all the articles for the review. Thanks also go to Tim Eden who provided advice on cancer, its treatment and the interventions included in previous versions of the review. The review authors would like to thank Dr Patricia Finlay for responding to our letter requesting further information. Thanks also go to Dr Toru Naito for translating a potential study in Japanese.

Characteristics of included studies  
(ordered by study ID)

Bensadoun 2008

**Methods**
Randomised, parallel group multicentre single blind study conducted in France, Tunisia and Morocco. Patients and carers not blinded. Primary outcome assessment made by blinded assessor. No evidence of funding apart from one collaborator is a consultant for pharmaceutical company who produced the tablets. Patients were recruited from May 2002 until June 2004

**Participants**
Adults with head and neck cancer. 306 patients randomised, 154 to miconazole tablet and 152 to miconazole gel. 6 patients in each group had no treatment, analysis conducted on 141 patient in each group. OP confirmed by direct mycological examination (culture)

**Interventions**
2 groups: miconazole tablet Lauriad 50 mg MBT (kept in mouth as long as possible) or 500 mg miconazole gel MOG (applied to gums) once daily for 14 days

**Outcomes**
Primary outcome success at day 14 (clinical eradication) and partial response was defined as improvement by 2 points on Murray Scoring Scale compared with score at baseline. Assessment made at 2, 6, 20 days, unclear which presented Secondary endpoint was success at day 7. Improvement in clinical symptoms, mycological cure (culture), recurrence rate and safety also reported

**Notes**
Modified intention-to-treat analysis - all randomised patients who received at least 1 treatment dose and had efficacy evaluation after randomisation. Non-inferiority statistical approach used Authors contacted about assessor blinding.

**Risk of bias**

### Finlay 1996

**Methods**
Randomised, parallel group study conducted in Scotland. The patients were not blinded. Information on withdrawals clarified by letter. No mention of funding but possible university funding. No dates for recruitment period

**Participants**
Adults with head and neck cancer. 77 enrolled, 73 completed.

**Interventions**
2 groups. Fluconazole 50 mg daily for 7 days. Amphotericin B 10 mg lozenge sucked for 14 days

**Outcomes**
Clinical and mycological eradication (culture). Assessment made at 2, 6, 20 days, unclear which presented

**Notes**
Communicating with authors changed randomisation assessment from Unclear to Yes (low risk of bias)

Finlay 1996  (Continued)

Incomplete outcome data addressed? Yes  Comment: Clarified by authors.

Free of selective reporting? Yes  Comment: Clinical and mycological eradication.

Free of other biases? Unclear  No information on funding.

Flynn 1995

Methods  Randomised, multicentre, parallel group study conducted in USA. Patient, carer not blind, assessor blind. Clear information on withdrawals given. Pfizer provided the drugs but no funding mentioned. No dates for recruitment period

Participants  Children with malignancies and immunocompromised including HIV (data presented separately). 186 enrolled, 182 received drugs, 92 (cancer patients) completed

Interventions  2 groups. Fluconazole 4 mg/kg suspension day 1 then 2 mg/day. Nystatin 4 ml USP suspension 4 times daily- swished in mouth and swallowed. Both for 14 days in total

Outcomes  Clinical and mycological eradication (culture). Assessment at 7 days or later

Notes  Study also included children with HIV, but data were presented separately. The dose of fluconazole was changed 1/4 way into study to 2 mg/kg day 1, then 3 mg/kg

### Hughes 1983

**Methods**

Randomised, parallel group study conducted in USA. Patient, carer and assessor blind. Unclear information on withdrawals given. Pharmaceutical company provided the tablets but no other information about funding. No dates for recruitment period.

**Participants**

Children and adults with mixed cancer. 64 enrolled, 56 completed.

**Interventions**

2 groups, placebo versus ketoconazole. 200 mg twice/day. 2 weeks duration.

**Outcomes**

Clinical and mycological eradication (culture). Assessment made at day 14.

**Methods**

Randomised, parallel group study conducted in Belgium. Patient, carer not blind, unclear whether assessor blind. Unclear information on withdrawals. No information about funding. No dates for recruitment period.

**Participants**

Patients with mixed cancer. 42 patients evaluated.

**Interventions**

2 groups. Ketoconazole tablets 200 mg every 8 hours. Nystatin 1000000 U suspension every 8 hours. Mean duration of ketoconazole was 13 days, nystatin 10 days, with maximum of 23 days for both groups.

**Outcomes**

Clinical eradication of oropharyngeal candidiasis or oral thrush. Microbiological eradication of pathogen (culture).

**Notes**

**Risk of bias**

### Oude 2004

**Methods**

**Participants**
Adults with mixed cancer. 279 randomised but only 252 eligible and evaluated. Of the 27 patients 23 were not eligible and 4 had no CRF.

**Interventions**
2 groups. Fluconazole capsules 100 mg per day for 10 days. Itraconazole capsules 200 mg per day for 15 days.

**Outcomes**
Clinical and mycological eradication at day 15 (culture). Evaluated at days 3, 7, 10, 15 and post-treatment assessment at day 42.

**Notes**
It is surprising that the study was not published for 7 years.

### Shechtman 1984

**Methods**
Randomised, parallel group study conducted in USA. Patient, carer and assessor blind. Clear explanation of withdrawals. Funding from pharmaceutical company and charity. No dates for recruitment period.

**Participants**
Adults with mixed cancer. 16 enrolled, 13 completed.

**Interventions**
2 groups, placebo versus clotrimazole 10 mg troche of clotrimazole 5 times/day (dissolving for 15 to 30 minutes). Duration 48 hours to 4 weeks.
Outcomes

Studena 1995

Methods
Randomised, parallel group study conducted in Slovak Republic. Patient, carer, not blind, unclear if assessor blind. Funding unclear. Recruitment 1.5.1992 until 1.5.1994

Participants
Adults with mixed cancer. 53 randomised and completed.

Interventions
2 groups. Fluconazole 10 days 100 mg OD or itraconazole 100 mg BID 15 days

Outcomes
Clinical and mycological eradication (culture) at 15 and 42 days.

Notes

### Risk of bias

<table>
<thead>
<tr>
<th>Item</th>
<th>Authors’ judgement</th>
<th>Description</th>
</tr>
</thead>
</table>
**Adequate sequence generation?**  Unclear  
Quote: “A randomised double blind trial...”. 
Quote: “...a randomised double blind technique was used to divide the patients into two groups...”

**Allocation concealment?**  Unclear  
No information given.

**Blinding of participants and carers?**  Yes  
Quote: “A randomised double blind trial...”.

**Blinding of outcome assessors?**  Yes  
Quote: “A randomised double blind trial...”.

**Incomplete outcome data addressed?**  Unclear  
Quote: “56 cancer patients with 60 episodes of oropharyngeal candidiasis were entered into the study between September 1976 and September 1977”
Quote: “Eight patients 8 episodes were considered evaluable”. Of the remaining 48 patients there were 52 episodes of infection
Comment: We don’t know which group these patients were in.

**Free of selective reporting?**  Yes  
Comment: Clinical and mycological eradication (culture).

**Free of other biases?**  No  
Quote: “If there was no clinical improvement after 5 days or the patients condition necessitated the start of systemic antifungal therapy, administration of the troches was discontinued”
Possible bias due to episodes rather than patients and data not independent
Comment: Pharmaceutical and government funding.

CONTRIBUTIONS OF AUTHORS
Jan Clarkson (JC) and Helen Worthington (HW) wrote the protocol and review. HW co-ordinated the review and wrote the letters to authors. JC and HW independently and in duplicate assessed the eligibility of trials, extracted data and assessed the quality of the trials. HW conducted the statistical analysis which was interpreted by JC and HW. Tasneem Khalid provided advice on the interventions and Stefan Meyer and Martin McCabe provided input on the cancer treatments and the assessment of the candidiasis.
