Synopsis ................................................................................................................. 14

1. Introduction ......................................................................................................... 16

   1.1 Biological Introduction .................................................................................. 17

       1.1.1 Neglected Parasitic Diseases ................................................................. 17

       1.1.2 Leishmaniasis ......................................................................................... 18

       1.1.3 Pathology ............................................................................................... 20

       1.1.4 Parasite life cycle .................................................................................. 22

       1.1.5 Treatment ............................................................................................... 24

       1.1.6 Diagnostics ............................................................................................ 25

       1.1.7 Leishmania surface coat ........................................................................ 30

       1.1.8 The Structure of the Lipophosphoglycan (LPG) ..................................... 32

       1.1.9 The role of the lipophosphoglycan ......................................................... 33
2.3.3 Synthesis of 1,2,3,6-Tetra-O-benzoyl-4-O-(2,3,4-tri-O-benzoyl-6-O-tert-butyldimethylsilyl-β-D-galactopyranosyl)-α-D-mannopyranose 30 .......................... 57

2.3.4 Synthesis of 2,3,6-Tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranose 33 ........................................ 58

2.3.5 Synthesis of 2,3,6-Tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranosyl hydrogenphosphonate, triethylammonium salt 34 .................................................. 62

2.3.6 Synthesis of 6-N-Biotinylaminohexanol 27 ........................................................................ 65

2.3.7 Synthesis of 6-N-Biotinylaminohexyl 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranosyl phosphate, triethylammonium salt 42 (protected form of the target compound 1) ................................................................................................................. 66

2.4 Attempted synthesis of biotinylated phosphosaccharide compounds using a monosaccharide bridge to biotin ........................................................................ 70

2.4.1 Attempted condensation of 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranosyl H-phosphonate 34 and Gal-linker-Fmoc derivative 43 ................................................................. 71

2.5 Synthesis of the target compounds 50, 51 and 52 with biotin moiety at the non-reducing end of the chain ........................................................................................................ 73
2.5.1 Synthesis of methyl 2,3,6-tri-O-benzoyl-4-O-(2,3,4-tri-O-benzoyl-β-D-galactopyranosyl)-α-D-mannopyranoside 38 .............................................................. 75

2.5.2 Synthesis of 6-N-Biotinylaminohexyl hydrogenphosphonate 28 ...................... 77

2.5.3 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-(6-N-biotinylaminohexyl phosphate), triethylammonium salt 44 ................................................................. 78

2.5.4 Synthesis of 2,3,6-Tri-O-benzoyl-4-O-(2,3,4-tri-O-benzoyl-6-O-tert-butyldimethylsilyl-β-D-galactopyranosyl)-α-D-mannopyranosyl hydrogenphosphonate, triethylammonium salt 36 ................................................................. 80

2.5.5 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate] triethylammonium salt 46 ..................................................................................... 81

2.5.6 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)], bistriethylammonium salt 47 ................. 83

2.5.7 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-
2.5.8 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-{2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)}], bistriethylammonium salt 48 ........................................85

2.5.9 Synthesis of methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-(6-N-biotinylaminohexyl phosphate), triethylammonium salt 50 (the first target compound) ...........................................................................................................90

2.5.10 Synthesis of methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-[β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)], bistriethylammonium salt 51 (the second target compound) ...........................................................................................................92

2.5.11 Synthesis of methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-{β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-[β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)]}, tristriethylammonium salt 52 (the third target compound) ...........................................................................................................93

2.6.0 Biological Results .........................................................................................................................95
2.6.1 ELISA assay

2.6.2 ELISA results

3. Experimental

3.1 General Procedures

1,2,3,6-Tetra-\(\text{O}\)-benzoyl-\(\alpha\)-D-mannopyranose 21

Acknowledgements

I would like to sincerely thank my supervisor, Dr Andrei Nikolaev, who through thick and thin stuck by me, and without his support this Thesis would not have been possible. Thank you to Prof Mike Ferguson who provided invaluable support and his valuable time in pushing this project forward.

To the people of the lab: Dr Nawaf Al-Maharik, Dr Dmitry Yashunsky, Dr Arthur Crossman, Dr Stephanos Ghilagaber, Dr Amina Slimani-Fersia, Dr Nuha Abdelwahhab, I would like to say thank you for all your assistance during the tough times and the tougher times.

To a fellow student, Alan Black, thank you for all your support and criticism through the years. You have also been there to answer the stupid questions and I wish you luck in your future endeavours.

To all the technical and administration staff: Gina Mackay, Brian Weryck, Kate Scott and Gail Guild, thank you for all your help, fixing the machines, fixing orders, fixing letters and submissions.

To the MAJF lab, thank you for all your help in deciphering the world of biochemistry. I am especially thankful to Lauren Sullivan who conducted all the biological testing and carried me through it.

To my thesis monitoring committee: Prof Ian Gilbert and Dr David Norman. Thank you for keeping me on the right track.

To my funding bodies: BBSRC and Axis-Shield, thank you for the funding.

And finally to everyone else: family, friends and loved ones, thank you for the many distractions welcome and unwelcome, without your help and support I would not be here.
Declaration

I hereby declare that the research described herein has been carried out and that this thesis is of my own work. This thesis has not been accepted in fulfillment of the requirements of any other degree or qualification. The research described herein was carried out in the College of Life Sciences, at the University of Dundee, under the supervision of Dr. A. V. Nikolaev.

Christopher W. Edgar

Certification

I hereby certify that Christopher W. Edgar, BSc Hons, has undertaken full-time research at the College of Life Sciences, University of Dundee, under my direction since October 2007, and that he has fulfilled the conditions of ordinance 14, so that he is qualified to submit this thesis for the degree of Doctor of Philosophy.

Dr. Andrei V. Nikolaev
Synopsis

Leishmaniasis, the disease caused by a genus of *Leishmania* protozoan parasite, is the second largest parasitic killer in the world (after malaria) responsible for an estimated 500,000 cases and 60,000 deaths each year worldwide. Visceral leishmaniasis infections (i.e., affecting internal organs like liver and spleen) are more complicated to diagnose due to the lack of visible symptoms. Current tests of the disease look for antibodies against the parasite, but these antibodies are expressed long after the infection. It has been found the *Leishmania* parasite excretes a unique phosphoglycan repeat unit:

\[ \ldots 6-\beta-D-Galp-(1\rightarrow 4)-\alpha-D-Manp-(1-OPO_2H) \ldots \]

By looking for this repeat unit, the diagnostic test will be checking for an active infection in the patient. It has been found that there are monoclonal antibodies to detect this uniquely excreted phosphoglycan. This provides a basis for a test kit, the biomarker (i.e., the phosphoglycan repeats), and the way to detect the biomarker. For the construction of a dipstick style test or an ELISA format assay, a chemically synthesised repeat unit phosphoglycan is needed to act as a positive control in a dipstick test or as a known comparison in an ELISA.

The synthetic phosphoglycan structure must also be anchored to a solid surface for testing. Biotin will be used as the anchor. It has shown many different applications in biotechnology and its very high affinity to the avidin proteins make it very useful. A
6-aminohexanol spacer arm (i.e., a linker) will also be included in the synthetic structures.

After original attempts to introduce the biotin moiety to the repeat unit at the D-mannose 1-phosphate, it was decided to change the strategy and integrate the biotin moiety via linker and phosphate at the D-galactose unit. This meant performing chain elongation from the reducing end, with the first disaccharide unit being capped at the D-mannose anomeric position with a methyl group. Below are examples of the targeted biotinylated phosphoglycan structures, which have been prepared in this project.

All three prepared biotinylated phosphoglycan structures were tested in ELISA assay using monoclonal IgG antibodies that recognises the repeat unit structure. They showed different activities in terms of antibody recognition and binding. The largest compound containing three repeats demonstrated the strongest signal. This positive result provides a foundation for novel assay formations and further immunological work.

1.1 Biological Introduction

1.1.1 Neglected Parasitic Diseases

Diseases such as malaria, leishmaniasis, African sleeping sickness (or African trypanosomiasis) and Chagas disease (or American trypanosomiasis) are all caused by insect-transmitted parasites. These diseases infect millions of people around the world and millions more are at risk of infection. Figure 1 gives an overview of the diseases their causative agents and the number of cases reported.

Figure 1 – Parasitic protozoan diseases [1]
1.1.2 Leishmaniasis

The origins of Leishmaniasis are unknown \cite{2}. There are records of lesions similar to the ones caused by leishmaniasis on tablets from the library of Ashurbanipal, King of Syria, from the 7th century BC. These are thought to be derived from earlier texts from 1500 to 2500 BC\cite{3}. It was first described in the modern era by Peter Borovsky, a Russian military surgeon who was conducting research into the etiology of an oriental sore in Tashkent, Uzbekistan. In 1898, he published the first accurate description of the causative agent, the parasite’s relation to the host tissues and even referred to it as a protozoa. However, his results were published in a Russian journal with low circulation so were not internationally acknowledged during his lifetime\cite{4}. In 1901 William Boog Leishman and Charles Donovan identified certain organisms in smears taken from the spleen of a patient who had died from “dum-dum fever” and called them trypanosomatids, which came to be known as Leishman-Donovan bodies\cite{5}\cite{6}.

1.1.2.1 Leishmaniasis Epidemiology

Leishmaniasis is a poverty related disease affecting the poorest people who are suffering from malnutrition, are being displaced and have a weakened immune system. Leishmaniasis is also related to environmental changes such as
deforestation, dam building and new irrigation schemes causing migration of non-immune people into endemic areas\cite{7}\cite{8}. The disease is prevalent and endemic in the tropics and sub-tropics covering large areas of Bangladesh, Pakistan, India, Africa, the Middle East, South and Central America and along the Mediterranean.

Figure 2: Geographical distribution of leishmaniasis (light blue) and co-infection with HIV (dark blue)

\cite{1}
1.1.2.2 Disease Burden

Recently the public health impact of leishmaniasis has been re-assessed and it was found that previous estimates were very low compared to the actual burden of the disease. It is now estimated that there are 2 million cases annually with 1.5 million of the cutaneous form and 500,000 of the visceral form and with around 12 million people infected throughout the 88 countries currently affected \[9\]. More surprising is that only 32 of the 88 countries that are affected by the disease actually have to report leishmaniasis infection. The actual numbers could be dramatically different \[7\].

1.1.3 Pathology

Leishmaniasis can present in 3 main forms each dependent on the area of the body infected (Fig 3).

![Figure 3- Leishmaniasis infections](image)

(1) Visceral  (2) Mucocutaneous  (3) Cutaneous
1. Visceral leishmaniasis (VL),\textsuperscript{[10][11]} infects the internal organs of the patient attacking the liver and spleen. If left untreated VL is fatal.

2. Mucocutaneous leishmaniasis (MCL),\textsuperscript{[12][13]} infects the mucous tissue of the nose and mouth. MCL infections self-heal but result in massive tissue damage and permanent disfiguration.

3. Cutaneous leishmaniasis (CL),\textsuperscript{[14][15]} infects the skin of the patient and results in self-healing ulcers that permanently disfigure the skin.

Worldwide visceral leishmaniasis makes up for about 25% of infected patients. Of these cases 90% are found in India, Sudan and Bangladesh\textsuperscript{[16]}. Temperature could play a part in the localisation of the parasite species in the host. Some species of the parasite causing cutaneous leishmaniasis cannot grow at the core body temperature while species causing visceral leishmaniasis can\textsuperscript{[17]}. The parasitic species causing the \textit{Leishmania} infections can be put into three large species groups and three less diverse groups\textsuperscript{[18]}. The parasites in these groups all have a similar physical appearance but with differing clinical manifestations.

3 Large Groups:

1. \textit{L. braziliensis} - cutaneous and mucocutaneous leishmaniasis in the Americas

2. \textit{L. mexicana} - cutaneous leishmaniasis in the Americas

The three small groups are *L. major* and *L.tropica* both causing cutaneous infections in Africa and the Middle East. *L. aethiopica* causes cutaneous infections in the North East of Africa.

1.1.4 Parasite life cycle

The parasite life cycle is a complex one surviving in the vector and the mammalian host and the many different environments this provides. The vector for the leishmania parasite is a certain species of sand-fly (Fig 4) from the genus *Phlebotomus*\(^{[19]}\).

![Sand-Fly vector for Leishmania](image)

**Figure 4** – Sand-Fly vector for *Leishmania*
Although there are around 500 different species of sand-fly (phlebotomine) only around 30 have been found to be vectors of the leishmania parasites\textsuperscript{[20]}. 

Figure 5 – The infectious cycle of *Leishmania*\textsuperscript{[21]}

Starting with a bite of an infected sand-fly into a non-infected host, the parasite promastigote metacyclic form is transmitted to the host. The parasite enters from vector to host with the anti-clotting factors which are injected normally by the sand-fly to ensure a steady blood flow. From here, the injected metacyclic parasites invade the host’s macrophages. In these macrophages the parasite differentiates
into the amastigote form and multiplies. The cells break down leaving the parasites free to infect other cells. This process repeats until treatment clears the infection or death. When another sand-fly, this time uninfected, takes a blood meal from the infected host it will ingest some of the parasites released from the macrophages. These enter the fly and attach to the mid-gut of the vector. From here they transform back to the procyclic form, multiply and travel to the mouth of the sand-fly where they are ready to be excreted in the next blood meal. During its complex life cycle the trypanosomatidae exhibits 2 distinct morphological states\textsuperscript{[22]}.

Promastigotes replicate in the midgut of the sand-fly vector and then transform into their infective metacyclic form. They are ingested into the macrophages, where they differentiate and proliferate as amastigotes in the phagolysosome compartment.

Good reviews have been published on the \textit{Leishmania}-sand fly interaction\textsuperscript{[23]}, the transmission mechanisms of the metacyclic promastigote\textsuperscript{[24]} and the metabolism of amastigotes inside human macrophages\textsuperscript{[25][26]}.

\section*{1.1.5 Treatment}

The most common treatment for leishmaniasis is a chemotherapy approach using pentavalent antimonials administered parenterally. The main compounds used are meglumine antimoniate and sodium stibogluconate, but the actions of these drugs are not totally understood\textsuperscript{[27][28]}. If the antimonials have no effect, alternative approaches are available using amphotericin B, pentamidine and paromomycin.
These approaches are expensive, moderately effective, toxic and the parasite is starting to show resistance\(^{29}[30]\). There is no vaccine for leishmaniasis but there are a number currently going through clinical trials\(^{31}[32][33][34]\). There is still a great need for treatments for leishmaniasis.

### 1.1.6 Diagnostics

Diagnosis of an active leishmaniasis infection can be tricky. In the cases of cutaneous and mucocutaneous infections this is straightforward as they present with skin lesions. Treatment can be immediate and the confidence in diagnosis is high. In the case of visceral leishmaniasis this is very different. Visceral leishmaniasis attacks the internal organs and if not treated in a timely manner is fatal. To complicate things further the symptoms caused by the infection are very similar to other diseases such as malaria\(^{35}\). The longer the patient spends untreated the more at risk the community becomes as the patient will act as a reservoir for the disease. To make matters worse the medical staff want to be sure of the diagnosis before the start of treatment due to the toxic and expensive drugs they will have to administer for the treatment length of 3 weeks\(^ {35}\).
1.1.6.1 Gold standard Test

The gold standard test (the best test) uses peripheral blood or aspirates from marrow, spleen, lymph nodes. These are gathered by biopsies of the specific area. The cells are then placed on a slide, stained and viewed under a microscope (Fig 6)[37].

![Figure 6 – Bone marrow aspirate smear of visceral leishmaniasis](image)

These biopsy and microscope techniques are very effective but require sterilised conditions, high level of training, high tech equipment and after care. This would be no problem in the developed world, but as most visceral leishmaniasis cases are found in the developing world (India, Sudan and Bangladesh) this equipment and expertise are not available to the vast populations.
What is required is a robust simple field test kit that can be run anywhere and with results that can be trusted.

1.1.6.2 Latex agglutination test - KAtex

The test has been developed to provide accurate results for the infection of visceral leishmaniasis patients in the field. The general procedure for the test is below:

1. Collect patient’s urine.
2. Take 1ml of urine and boil for 5 mins and allow to cool.
3. Add 50ul of the boiled urine to the reaction zone on the test plate.
4. Add 1 drop of the testing latex on to the sample of urine.
5. Stir both liquids to form homogenous mixture.
6. Tilt the plate with a rotating action – clockwise and anti-clockwise for 2 mins.
7. After 2 mins, read the degree of agglutination obtained.

The test works by using antibodies bound to the latex, these antibodies then bind to the antigen in the urine, with agglutination as a positive result. The results from the test can be read fairly quickly and can be done by eye, so no complicated machines are required. This test has drawbacks when it comes to the “field setting”. The boiling of the urine is possible in most settings but can cause problems in some. The tests themselves have to be kept at 4 °C and the kit itself is only for a minimum of
100 tests\textsuperscript{[38]}. The sensitivity of the test needs to improve as in a study the KAtex test result was positive in 87% of a large sample, the largest evaluated to date, a sensitivity $> 95\%$ is ideal for a diagnostic test\textsuperscript{[39]}.

\textbf{1.1.6.3 Lateral Flow test – rK39 RDT}

This dipstick style lateral flow test which can provide a result using a drop of blood collected from a patient and provide results in around 10 min. Fig 7 below provides an overview to how the test is run.

![Fig 7 – rK39 dipstick test\textsuperscript{[35]}](image)

These tests are very simple to run and only require a fresh drop of blood collected from a whole blood sample and a few drops of the buffer solution to give a result. The testing reagent is thought to be antibodies that recognise other antibodies in the blood sample, these are already present on the strip so no addition of reagents is necessary. Through capillary action the sample passes along the strip where it comes into contact with the testing antibodies that bind any parasitic antibodies found in
the blood. The test gives the results as either positive or negative. These tests are supplied individually wrapped, can be stored at room temperature and need no other equipment\textsuperscript{[38]}. By looking for specific antibodies against the parasite; this is very good in patients with an active infection. The problem is that once the infection has been treated and cleared, the body continues to produce anti-bodies against the past infection. Due to the continual expression of antibodies after the infection has past (around 3-4 months after) this test will continue to read positive for an infection\textsuperscript{[40]}.

What is needed is a test-kit that brings the robustness of the rK39 RDT test, with detection of an active infection allowing treatment to stop when the infection stops. So the test would need to detect something that is parasite specific, and only present when the parasite is active in the patient.
1.1.7 Leishmania surface coat

The surface coat of the *Leishmania* parasite is very complex and is very important in the survival and infectivity in both the insect vector and mammalian host. Many of the major cell-surface macromolecules found on the surface are anchored to the plasma membrane by glycosylphosphatidylinositol (GPI) anchors. Glycoconjugates expressed by the *Leishmania* parasite during the promastigote stage, are seen in Fig 8 \([41][42][43]\).

![Figure 8](image.png)

**Fig 8 – Representation of the major cell-surface glycoconjugates of Leishmania**\(^{[44]}\)

The lipophosphoglycan (LPG) is a complex glycolipid forming a dense layer on the cell surface. The dense layer is made up with around \(6 \times 10^6\) copies per promastigote cell. The LPG structure is made up of a GPI anchor linked to a phosphoglycan backbone of a repeat unit made up of Gal\(\beta_1-4\)Man\(\alpha_1\)-PO\(3\)H known as the phosphoglycan repeats (PG).
Glycoproteins such as GP46\textsuperscript{[46]}, promastigote surface protease GP63\textsuperscript{[47]} and secreted forms of proteophosphoglycans\textsuperscript{[48]} and finally a family of heterogeneous class of structurally related densely packed low-molecular mass glycoinositolphospholipids (GIPLs) can be found on the surface\textsuperscript{[41][42]}. 

Figure 9 – \textit{Leishmania} surface coat\textsuperscript{[45]}
1.1.8 The Structure of the Lipophosphoglycan (LPG)

The LPG has 3 main parts to its structure; the first is a phosphoinositol lipid anchor which binds to the cell surface holding the entire structure in place. Bound to this is a phosphosaccharide core which is also bound to the second important structure, the repeat domain, which is made up of the repeat unit Galβ1-4Manα1-PO₃H. The final part is an oligosaccharide cap to terminate the chain\[(42]\]. The anchor and phosphosaccharide core are much conserved in the *Leishmania* parasite. There are conserved areas in the repeat unit structure (the backbone) but it does contain some very species specific and life cycle specific variations. This can be clearly seen in Fig 10.

![Diagram of LPG structure](image)

**Fig 10 - LPG differences by species**

L. *donovani* promastigote [49] [50], \(X = Y = H\)

L. *mexicana* promastigote [51] [52], \(X = \beta\text{-D-Glc-p-1- (0.25), } Y = H\)

L. *major* procyclic promastigote [53] [54] [55], \(X = \beta\text{-D-Gal-p-1- (0.52), } \beta\text{-D-Gal-p-1- (0.25), } \beta\text{-D-Ara-p-1- (0.09), } Y = H\)

L. *major* metacyclic promastigote [53] [54] [55], \(X = \beta\text{-D-Gal-p-1- (0.31), } \beta\text{-D-Gal-p-1- (0.06), } \beta\text{-D-Gal-p-1- (0.45), } Y = H\)

L. *aethiopica* promastigote [56], \(X = \beta\text{-D-Gal-p-1-3-β\text{-D-Gal-p-1- or β-D-Galp-1-; } Y = α\text{-D-Manp-1- (0.35)\}}

L. *mexicana* amastigote-specific proteophosphoglycan [57], \(Y = H\)

\[
\begin{align*}
\beta\text{-D-Glc-p-1-β-D-Glc-p-1-} & \\
α\text{-D-Manp-1-PO₃H-6-β-D-Galp-1-3-β-D-Glc-p-1-} & = X \\
α\text{-D-Manp-1-β-D-Galp-1-4-β-D-Glc-p-1-} & \\
z & = [α\text{-D-Manp-1-2β-D-Manp-1-PO₃H-6-β-D-Glc-p-1-3-β-D-Glc-p-1-}] \end{align*}
\]
The different species of *Leishmania* alter their LPG structure by adding branched sugars at different points, but always conserving the repeat unit backbone.

### 1.1.9 The role of the lipophosphoglycan

The characteristics and role of the LPG have been discussed extensively in reviews [58][59]. The LPG is associated with many important steps in the Leishmania infectious life cycle of both the vector and host [41][42][43]. It has been seen in knock out studies (knocking out genes used in the biosynthesis of the LPG) that the LPG is needed for the survivability of the parasite [21][58][59]. This makes the area of LPG biosynthesis an area of great interest.
1.1.10 The biosynthesis of the lipophosphoglycan repeat unit.

The Galβ1-4Manα1-PO₃H repeat unit which makes the backbone of the LPG structure is made by sequential addition of mannosylphosphate and galactose\[^{60}\] performed by a mannosylphosphate transferase (MPT) and a glucosyltransferase (GT) as seen in Fig 11.

![Figure 11 – Biosynthesis of LPG repeat domain](image)

The repeat unit structure is not specific to the LPG; it is a structural component in many other glycoconjugates such as secreted and membrane proteins including sAP and PPGs. Since the repeat unit is used in many structures unique to the parasite including the extra-cellular LPG and secreted PPG's, it was thought that these repeat unit structures might be detectable. If it is possible to detect these structures then it would give a valuable parasite specific biomarker.
1.1.11 Detection of phosphoglycan repeats

In the lab of Marcel Hommel in the Liverpool School of Tropical Medicine a low molecular weight antigen (LMWA) was identified in the urine of visceral leishmaniasis patients\cite{61}. The methods they employed included; Capture ELISA, enzyme detection, trichloroacetic acid treatment, ethanol and acetone precipitation, Periodate treatment, Phenol-water extraction, Lipid extraction, Biotinylation, Affinity transfer blotting, Triton X-114 phase separation, Purification of GIPL’s and finally detection by Leishmania anti-glyconjugate monoclonal antibodies. Unfortunately the group were unable to determine the structure of this LMWA they found, all they could say was that it was carbohydrate in nature and had very good binding with monoclonal antibodies raised against the LPG\cite{62,63}. This meant the structure found in the urine of the infected patient was some form of phosphoglycan repeat structure fragments from either the LPG or a PPG\cite{63a}.

This was further confirmed by Ferguson’s group in Dundee who were able to identify the phosphoglycan repeat structures by electrospray mass-spectrometry\cite{64}. The methods used were able to confirm the structure of the LPG fragments and could even detect any branched sugars from the various parasites. This method will enable us to type the LPG’s and PG’s in the biological samples such as urine.
1.1.12 A Possible New Test-kit for Leishmaniasis.

With the results talked about in the previous section it is now possible to think about a new diagnostic test-kit for leishmaniasis\cite{38}\cite{39}\cite{40}. The main problem with the rK39 dipstick test was that it could not detect when an infection had cleared because it detected the antibodies against the parasite. The new test looks for the antigen from parasite, this means when the parasite is gone (the patient is uninfected) there will be a negative result meaning treatment can halt. The urine of the patient will be tested, thus avoiding having to take blood from patients who live in areas with very high HIV+ infection rates.

By maintaining the idea of a lateral flow test (dipstick)(Fig 12 and 13) we can design a test using the phosphoglycans from the parasite and the antibodies to recognise them.

![Diagram](image)

Figure 12 & 13 – lateral flow test ideas.
In this test, the urine (infected or not) is placed at the start of the strip and is immediately mixed with the anti-phosphoglycan antibodies bound to a marker. For an infected sample it is expected any phosphoglycans (PGs) in the urine will be picked up by the antibodies. Through capillary action the urine/antibody mixture is washed along the plate where it comes across synthetic PGs. For an infected sample there should be no binding with the synthetic PGs due to all antibodies being blocked by PGs found in the urine. For an uninfected sample there should be binding with the synthetic PGs. The capillary action continues to move the sample to end point where the test is complete. For an uninfected patient there would be 2 bands, one to show binding with the synthetic PGs and another to show excess antibodies at the end (Fig 12). For an infected patient there would be one band, at the end, as there should be no binding with the synthetic PGs due to all antibodies being blocked by PGs found in the urine.
For this test to work synthetic phosphoglycans are needed, thus providing the positive and negative comparison. They must be designed so they are recognised as the repeat unit structure and they must contain a region that can be bound to a solid surface for testing. A selection of repeat unit lengths (1 - 3) should be synthesised (Fig 14). Once synthesised, the compounds will undergo ELISA experiments to measure the binding of the monoclonal antibodies to establish how many repeat units are needed. Once this is complete the next steps will involve comparing the binding to antibodies and urine samples of infected patients. The synthesis of these compounds makes up the core topic of this thesis.

![Figure 14 – Synthetic phosphoglycan repeats linked to biotin moiety](image-url)
1.2 Chemical Introduction

1.2.1 Chemical synthesis of *Leishmania* LPG repeats

The development of synthetic approaches to phosphoglycans in general and *Leishmania* LPG in particular is not an easy task because of the hydrolytic lability of the phosphodiester bridges, which link the repeating units through the anomeric OH of D-mannose and the 6-OH of D-galactose. Wide-ranging reviews of *Leishmania* phosphoglycans have been published. These reviews cover a variety of approaches, stepwise, blockwise, polymer-supported and polycondensation, for the chemical synthesis of phosphoglycans.

![Figure 15 - Structure of the LPG of *L. donovani* and *L. major*](image-url)
As described before the LPG domain contains the oligosaccharide cap, the repeat domain and the GPI anchor. The size of the repeat domain depends on the parasites stage of development. Many groups have been working on the synthesis of the LPG concentrating on different areas. The Vishwakarma \cite{68}, Fraser-Reid \cite{69} and Seeberger \cite{70,71} groups synthesised the LPG cap domain. Synthesis of the *Leishmania* LPG core has been performed jointly by two groups: Oscarson and co-workers \cite{72} and Konradsson and co-workers \cite{73,74}. The LPG repeat domain has been worked on by two main groups, Nikolaev’s group from University of Dundee and Vishwakarma’s group from New Delhi. Both have attempted synthesis of the repeat units using different synthetic strategies. Since the important synthetic aim of the project is to produce repeat unit structures the different approaches will be discussed.

### 1.2.2 Nikolaev and co-workers

The first successful syntheses of the *Leishmania* phosphoglycans were achieved by the Dundee University based group \cite{75,76} by exploiting H-phosphonate chemistry. Several successful syntheses of *L. donovani* phosphoglycans containing 2 and 3 repeat units and with the cap unit attached were synthesised (Scheme 1) using the stepwise approach to chain elongation. The glycosyl H-phosphonate route was proven to be the method of choice for the efficient and reliable assembly of various phosphodiester linkages \cite{77}.
Protected tetrasaccharide phosphate 8 was synthesised by the coupling of the 
disaccharide H-phosphonate 4 and the disaccharide 6 with one free hydroxyl group,
followed by the removing of the DMT protecting group. Addition of another H-
phosphonate 4 and subsequent oxidation yielded the hexasaccharide diphosphate 7 after de-O-tritylation. Further chain extension using the disaccharide H-phosphonate 5 and compounds 7 followed by global deprotection gave the octasaccharide phosphoglycan 9. Protected fragments 7 and 8 also underwent global deprotection giving compounds 10 and 11, respectively.
Using the stepwise addition of H-phosphonate units 4 and 12 the branched phosphoglycan of \textit{L. mexicana} 13 was synthesised (Scheme 2)\textsuperscript{[79]}. In addition, several LPG fragments from \textit{L. major} were also prepared. \textsuperscript{[80][81][82][83][84]}

\textbf{Scheme 2} – Stepwise strategy to \textit{L.mexicana} LPG
A blockwise approach was also developed by Nikolaev et al.\textsuperscript{[85]} this involves the condensation of two phosphodiester blocks: the H-phosphonate derivative 15 and 6'-hydroxyl acceptor 14 for the synthesis of the hexaglycosyl triphosphate 16, which is a terminal fragment of the phosphoglycan portion of \textit{L. donovani} LPG (Scheme 3).

Scheme 3 – Blockwise strategy to \textit{L. donovani} phosphoglycan
1.2.3 Vishwakarma and co-workers

Vishwakarma and co-workers also described an iterative synthesis of the *L. donovani* phosphoglycan 19 (Scheme 4), as well as the branched phosphoglycan 20 of *L. major* (Scheme 5) using traditional solution phase chemistry.

Scheme 4 – The preparation of *L. donovani* phosphoglycans
Scheme 5 - The preparation of the branched phosphoglycan of *L. major*.
1.2.4 Anchor and Spacer Selection

The anchor part of the synthetic phosphoglycans 1-3 (Fig 14) must be stable during the chemical synthesis and when needed bind to a solid surface. The anchor that was chosen was biotin (Fig 16); vitamin H or Coenzyme R has been used for many biological applications. By biotinyling unknown proteins or compounds in solution they can be anchored and identified. The anchoring occurs with the use of avidin proteins which bind biotin with a very high affinity ($K_d \sim 10^{-15}$ mol/L). This provides the biochemists with the ability to capture unique compounds from solution.

![Figure 16 – Biotin](image)

Biotin will be incorporated into the synthetic phosphoglycans with a spacer molecule which will be 6-aminohexanol. The spacer is used just to separate the phosphoglycan repeats and the biotin. There has not been a great deal of work from a synthetic carbohydrate chemistry perspective using biotin but a paper modifying biotin [89] was published from the laboratory of Nikolaev and will form the basis of chemistry involving biotin.
2. RESULTS AND DISCUSSION
2.1. Aims of the project

A biomarker for the *Leishmania* parasite has been identified in the lab of Mike Ferguson in Dundee. It was found that this biomarker is a \(-\text{6-}\beta\text{-D-Galp-(1-4)-}\alpha\text{-D-Manp-(1-OPO}_2\text{H-}...\) (Fig 17) repeat unit of the repeat domain of the lipophosphoglycan (LPG), the most abundant macromolecule on the surface of promastigote forms of all *Leishmania* species.

This repeat unit was found to be detectable in the urine of an infected patient, and since this phosphoglycan structure is parasite specific it gives a very good basis for a diagnostic test. Furthermore, since this phosphoglycan is parasite specific once the infection has been treated there will be no biomarker present in the patient. In further work monoclonal antibodies were identified that recognise this structure and could be used as part of the test kit. So, the idea of a test kit was put together (Fig 18) where the urine of
an infected patient would be tested with the antibodies to give a result either positive for an active infection (Fig 18) or negative for no infection (Fig 19).

Fig 18 – Positive test

Fig 19 – Negative test
With this style of dipstick test a positive control is needed, so synthetic compounds of the repeat unit must be synthesised. The repeats must be recognised by the antibody and provide detectable binding to provide a result. These repeats must also be able to bind with a surface on which the testing can occur.

Three target compounds 1-3 (Fig 20) were decided upon of different repeat unit lengths, all attach to a biotin moiety that can be used to anchor the compounds to an avidin-coated surface.

![Diagram of target compounds 1-3](image)

**Fig 20 – Original target compounds: biotinylated LPG fragments 1-3**
After the synthesis of the compounds they will undergo biological testing in an ELISA assay to measure the binding with the antibody to establish which compound length is most suitable.

**2.2. General synthetic design**

The chemical preparation of compounds 1-3 was attempted and appeared to be unsuccessful (see Section 2.3.7), although an alternative strategy was developed later (see Section 2.5), which was successful for the preparation of different structures containing one, two and three repeat units connected to a biotin moiety. This was completed using the synthetic schemes which contained a few general steps:

1) Preparation of selectively protected monosaccharide and disaccharide derivatives.

2) Preparation of protected H-phosphonate derivatives.

3) Preparation of protected phosphoglycan structures using the glycosyl H-phosphonate condensation method (including biotin addition).

4) Total deprotection through de-O-benzoylation.
2.3 Synthesis of 6-N-Biotinylaminoethyl 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p'-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranosyl phosphate, triethylammonium salt 42

A retrosynthetic scheme that enables the synthesis of the target compounds has been identified (Scheme 8). The building blocks required for the compounds 1-3 are a modified (with 6-aminohexanol linker) biotin derivative 27 and the repeat unit β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl H-phosphonate derivative 34.
For the additional target compounds 2 and 3 extra repeat units will be added through the chain elongation using the protected disaccharide H-phosphonate derivative 34. This was to be done after the incorporation of the biotin derivative to the first repeat.

2.3.1 Synthesis of 1,2,3,6-Tetra-O-benzoyl-α-D-mannopyranose 21

The glycosyl acceptor 21 (Scheme 9) for the disaccharide synthesis is a α-D-mannopyranose derivative protected at positions 1,2,3 & 6 with a benzoyl protecting group leaving the hydroxyl at position four free\textsuperscript{[91]}. This can be done by selective benzoylation using a dropwise addition of a strict 4 eq. of benzoyl chloride to a solution of D-mannose in pyridine at -40 °C.

![Scheme 9 – Preparation of the glycosyl acceptor 21](image)

Use of a strict 4 eq. of the reagent means the benzoyl chloride will react with the most reactive HO-groups first leaving the least reactive unprotected. In the case of D-mannose 4-OH is the least reactive group giving the required selectivity. Derivative 21 was
recrystallised from ethyl acetate and n-hexane giving crystals with a melting point of 184-185 °C.

2.3.2 Synthesis of 2,3,4-Tri-O-benzoyl-6-O-tert-butyldimethylsilyl-α-D-galactopyranosyl trichloroacetimidate 24

The D-galactopyranosyl trichloroacetimidate 24 (Scheme 10) was synthesised starting from D-galactose.

D-Galactose was firstly reacted with tert-butyldimethylsilyl chloride in pyridine for 2 hours. This provided a silyl protecting group at position 6, which would become important in further steps. Once the silyl protection was in place, benzoyl chloride (10 eq) was
added to protect the rest of the free hydroxyls of D-galactose. After a work-up and purification on silica gel this gave a fully protected galactose derivative 22 in a good yield of 82%. The next step required the formation of the hemiacetal by removing the benzoate from the anomeric position. This was done using two methods, the first used dimethylamine (2M) in THF and this method took around 12 hours and gave a yield of 59% \textsuperscript{90}|\textsuperscript{91}. The second method took considerably longer at 30 hours but the yield was higher at 75%; this method used ethylenediamine and acetic acid in THF\textsuperscript{92}. Both methods were used during the repeated syntheses of the hemiacetal 23. Formation of the glycosyl donor 24 from the hemiacetal was done using trichloroacetonitrile and a catalytic amount of cesium carbonate in DCM \textsuperscript{93}|\textsuperscript{94}. The reaction took around 1 hour to complete, with the yield of 64%. The formation of the glycosyl trichloroacetimidate 24 was verified with by \textsuperscript{1}H and \textsuperscript{13}C NMR. From the \textsuperscript{1}H NMR the signal for the NH of the trichloroacetimidate at 8.69 ppm, can be clearly seen.
2.3.3 Synthesis of 1,2,3,6-Tetra-O-benzoyl-4-O-(2,3,4-tri-O-benzoyl-6-O-tert-
butyldimethylsilyl-β-D-galactopyranosyl)-α-D-mannopyranose 30

With the synthesis of the glycosyl donor 24 and the glycosyl acceptor 21 the derivative to
form is the protected disaccharide 30 (Scheme 11).

![Scheme 11 – Preparation of the disaccharide 30](image)

The glycosylation of the 4-OH D-mannose acceptor 21 with the trichloroacetimidate
galactose donor 24 was catalysed by Trimethylsilyl trifluoromethanesulfonate (TMSOTf),
with molecular sieves 4Å to ensure anhydrous conditions\[^{95}\]. The reaction proceeded
smoothly with the major product being the β−linked disaccharide 1,2,3,6-tetra-O-
benzoyl-4-O-(2,3,4-tri-O-benzoyl-6-O-tert-butyldimethylsilyl-β-D-galactopyranosyl)-α-D-
mannopyranose 30 formed in a 72 % yield.
2.3.4. Synthesis of 2,3,6-Tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranose 33

2.3.4.1 Method A

![Scheme 12 – Preparation of the disaccharide 33](image)

From derivative 30 removal of the silyl protection group was carried out using a mixture of 40 % aq. HF and acetonitrile (1:3) at 0 °C[^96]. This removed the silyl group at position 6 and provided the disaccharide 31 (Scheme 12) in a 95 % yield. This was further proved by the complete disappearance of the tert-butyldimethylsilyl signals in the $^1$H and $^{13}$C NMR of 31. Compound 31 was then re-protected at position 6 of the D-galactose residue, this time with a p,p’-dimethoxytrityl protecting group. The reason for the replacement of the protecting group at this stage and not at the beginning of the synthesis of the
disaccharide 30 is due the very acid sensitive nature of the \( p,p' \)-dimethoxytrityl protection (which proved to be highly beneficial during further phosphosaccharide chain elongation).

![TBS protection](image1.png) ![DMT protection](image2.png)

Scheme 12a – TBS and DMT protecting groups

If the \( p,p' \)-dimethoxytrityl group was present from the beginning of the synthesis during the previous step of glycosylation (see Section 2.3.3) it would have been cleaved. This would have resulted in two free hydroxyl groups during the glycosylation reaction resulting in many side products. By changing the TBS protecting group to the DMT (Scheme 12a) this gives fast effect removal, 2 min for \( p,p' \)-dimethoxytrityl compared with 3 h for silyl. In addition, the \( p,p' \)-dimethoxytrityl derivatives can be easily identified by the bright orange colour they give when detected on TLC plates with a mixture of sulphuric acid-water-ethanol (15:85:5). Tritylation of compound 31 was carried out with \( p,p' \)-dimethoxytriphenylmethyl chloride in pyridine. This took around 15 h to complete giving the derivative 32 in an 82% yield. The formation of the hemiacetal 33 was carried out
using the dimethylamine method\(^{[90][91]}\) yielding 70% in 20 h and the ethylenediamine method\(^{[92]}\) was complete in 40 h giving a yield of 75%. Dimethylamine was used as the method of choice in this step due to the lower reaction time. With the hemiacetal disaccharide 33 prepared in a good yield over the 4 steps (starting from monosaccharide compounds 21 and 24), the building block for the H-phosphonate disaccharide repeat unit derivative, was now available.

### 2.3.4.2 Method B

Another method for the formation of this DMT protected disaccharide 32 was designed. This method (Scheme 13) reduces the number of steps and purifications needed to synthesise this compound.\(^{[93]}\)

Scheme 13 – Alternative synthesis of the disaccharide 32
The pentaacetate of β-D-galactose underwent anomic deprotection with dimethylamine in THF.\textsuperscript{[90]}[91] After 1 h it could be seen (monitoring by TLC) the reaction was complete, and the crude hemiacetal derivative was taken straight into the next step. The formation of the trichloroacetimidate 29 was carried out in DCM with trichloroacetonitrile and a catalytic amount of cesium carbonate\textsuperscript{[97]}. After 2 h the reaction was worked up and the product was purified. This gave the trichloroacetimidate 29 in a yield of 80% for the two steps. The glycosylation reaction between derivative 29 and the tetrabenzoate 21 was carried out with TMSOTf as the catalyst, and run for 30 min at -40 °C\textsuperscript{[95]}[97]. Purification of the reaction products resulted in the disaccharide 39 in a yield of 88%. The disaccharide 39 then underwent a deprotection step to remove all the acetate groups from the D-galactose residue, which was achieved by using HCl in MeOH. This method is highly selective to cleave O-acetyl protecting groups in the presence of benzoic esters\textsuperscript{[98]}. Once the de-O-acetylation was complete the reaction was quenched and worked-up. The next step was to dissolve the product in pyridine and add the \( p,p' \)-dimethoxytriphenylmethyl chloride; this was left for 20 h after which benzoyl chloride was added and the reaction mixture was left for a further 15 h\textsuperscript{[97]}. The reaction was then stopped and worked-up; after the purification the disaccharide 32 was isolated in a 91% yield for the 3 steps.
2.3.5 Synthesis of 2,3,6-Tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-\((p,p'\text{-dimethoxytrityl})-\beta\text{-galactopyranosyl}]\text{-}\alpha\text{-D-mannopyranosyl}
hydrogenphosphonate, triethylammonium salt 34

Scheme 14 – Preparation of the disaccharide H-phosphonate with PCl$_3$, imidazole and Et$_3$N

The synthesis of the H-phosphonate derivative 34 was achieved via the disaccharide hemiacetal 33 (Scheme 14). Phosphitylation of the hemiacetal was carried out using trimeridazolylphosphine, which was prepared in situ from PCl$_3$, imidazole and Et$_3$N, followed by hydrolysis with aq. TEAB buffer solution (pH 7.8)$^{[99][100]}$. This provided the glycosyl H-phosphonate derivative 34-\(\alpha,\beta\) in a very good 95 % yield, but as an anomeric mixture at the D-mannose residue with \(\alpha/\beta\) ratio of 12:1. To proceed on in the synthetic strategy a ratio of >20:1 would be preferred to ensure the correct anomeric configuration. To improve the \(\alpha/\beta\) ratio, the derivative 34-\(\alpha,\beta\) was reacted with silver triflate and methanol for 40 min at room temperature$^{[101]}$. This allowed degradation (solvolysis) of the \(\beta\)-H-phosphonate back to the original hemiacetal 33 (Scheme 15). The glycosyl \(\beta\)-H-phosphonate (with equatorial H-phosphonic moiety at C1) is known to be less stable than the corresponding \(\alpha\)-anomer (with axial H-phosphonic moiety at C1), which is favoured
by the anomeric effect \(^{[102]}\). It was seen by \(^{31}\)P NMR that there was no \(\beta\)-anomer present and the pure \(\alpha\)-anomer 34 was isolated in a 50% yield. The hemiacetal 33 was recovered and used again to prepare the disaccharide H-phosphonate.

Scheme 15 – ‘Correction of the configuration’ with silver triflate and MeOH

Due to the anomeric mixture formation with PCl\(_3\), imidazole and Et\(_3\)N and a moderate yield in the 2-step synthesis (formation of the H-phosphonate and ‘correction of the configuration’) another method was tried for the formation of the H-phosphonate 34.

Scheme 16 – Preparation of the disaccharide H-phosphonate with salicyl chlorophosphite
This method[^103][^104] used salicyl chlorophosphite and Et$_3$N in acetonitrile reacting with derivative 33 (Scheme 16) for 1 h at room temperature, followed by hydrolysis with aq. TEAB buffer solution (pH 7.8). After purification the H-phosphonate 34 was isolated in a 98% yield and by $^{31}$P and $^1$H NMR it could be seen that there was only the $\alpha$-anomer. As this method gave pure $\alpha$-H-phosphonate, there was no need to correct the configuration.

This 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-($p,p'$-dimethoxytrityl)]-$\beta$-D-galactopyranosyl-$\alpha$-D-mannopyranosyl hydrogenphosphonate 34 is the first building block and also the repeat unit in the synthetic strategy. The next building block to synthesise is the biotin component.

Scheme 17 – Preparation of 6-\(N\)-biotinylaminohexanol 27

Synthesis of the biotin derivative 27 (Scheme 17) was achieved by converting D-biotin to the \(p\)-nitrophenyl ester 26 and then addition of the spacer molecule 6-aminohexanol\textsuperscript{[106]}. Compound 27 is the building block that will react with the disaccharide H-phosphonate to form the first of the target molecules. A mixture of D-biotin, \(p\)-nitrophenyl trifluoroacetate and \(p\)-nitrophenol in pyridine was heated to 55 °C for 2 h \textsuperscript{[105][106]}. The D-biotin \(p\)-nitrophenyl ester 26 was recrystallised from ethanol, giving a yield of 72 % of the crystals. The ester 26 was added to 6-aminohexanol in DMSO, and the mixture was left for 20 h \textsuperscript{[105]} at room temperature. The derivative 27 was precipitated by the addition of acetone and diethyl ether giving 27 in a good 80 % yield. This gave our final building block
in this synthetic strategy leaving the next step the condensation between the protected
disaccharide H-phosphonate 34 and the 6-N-biotinylationhexanol 27.

2.3.7 Synthesis of 6-N-Biotinylationhexyl 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-
O-benzoyl-6-O-(p,p'-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-
mannopyranosyl phosphate, triethylammonium salt 42 (protected form of the target compound 1)

Before using the valuable disaccharide H-phosphonate 34 for the condensation with the
biotin derivative 27, a trial experiment using 2,3,4,6-tetra-O-benzoyl-α-D-glucopyranosyl
H-phosphonate 40 (Scheme 19) was performed. Compound 40 (Scheme 18), in turn, was
synthesised from the O-benzoylated D-glucose hemiacetal 53, which was kindly donated
by Dr Amina Fersia.

This was converted to the H-phosphonate derivative 40\textsuperscript{[107][108]} by reacting it with tri-
imidazolylphosphine formed \textit{in situ} from PCl\textsubscript{3} and imidazole in the presence of
triethylamine, followed by hydrolysis with aq. TEAB buffer solution (pH 7.8). This gave the monosaccharide H-phosphonate in a good 78 % yield. The next step was to condense this compound with the biotinyl derivative 27 (Scheme 19).

![Scheme 19 – Preparation of 6-N-biotinaminohexyl 2,3,4,6-tetra-O-benzoyl-α-D-glucopyranosyl phosphate](image)

The compounds 27 and 40 were combined together using pivaloyl chloride as the condensing agent. After 90 min at room temperature, I$_2$ in a pyridine-water (95:5) solution was added to oxidise the intermediate H-phosphonic diester to the phosphate. After workup and purification on silica gel, the phosphodiester compound 41 was isolated in a 77 % yield and the structure was proved by $^1$H, $^{13}$C and $^{31}$P NMR data. This trial experiment was a good indicator that the condensation of the larger disaccharide unit should progress well and the conditions are well suited.
The condensation of the protected disaccharide H-phosphonate 34 and the modified biotin 27 (Scheme 20) was carried out in the same conditions as the model synthesis (Scheme 19) had been run. It was noticed after the oxidation step that the biotin containing sugar derivative 42 was very polar on TLC and running just slightly above the unreacted biotin compound 27. This made the purification of the biotin sugar phosphate 42 a lot more complicated to get a pure compound. On TLC it was also seen there was much cleavage of the H-phosphonate group in compound 34, which resulted in the disaccharide hemiacetal 33 as the major product. After workup and purification on silica gel a small amount of target compound 42 was recovered (8 %). This was just enough to run $^1$H and $^{31}$P NMR spectra to prove the structure of the product.

Scheme 20 – Preparation of 6-N-biotinylaminohexyl 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranosyl phosphate
Due to the very low yield of the compound and the difficulty in purifying biotinylated protected carbohydrate phosphates it was decided to abandon the method of biotin integration through a phosphate group at the beginning of the chemical chain elongation. Instead it was decided to look for a method introducing biotin later in the synthetic scheme thus avoiding the polarity issues that led to purification problems.
2.4 Attempted synthesis of biotinylated phosphosaccharide compounds using a monosaccharide bridge to biotin

A retrosynthetic scheme that incorporated the biotin moiety later in the synthetic scheme, while reducing the polarity of the overall protected molecule, was identified (Scheme 21).

Scheme 21 – Retrosynthetic approach using the monosaccharide bridge
The synthetic strategy enabled integration of the biotin moiety as a final step, allowing a stepwise or blockwise building approach to be used for chain elongation by simple removal of the $p,p'$-dimethoxytrityl protecting group. The D-galactose linker derivative 43 can be coupled with the repeat unit H-phosphonate 34 by a condensation at the position 6. Once the corresponding trisaccharide monophosphate is formed, removal of the Fmoc protection from amino group in the linker and coupling with the biotin $p$-nitrophenyl ester 26 should be possible. The first reaction to carry out was to test the coupling between the disaccharide H-phosphonate 34 and the Gal-linker-Fmoc derivative 43.

2.4.1 Attempted condensation of 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p'-dimethoxytrityl)-β-D-galactopyranosyl]-α-D-mannopyranosyl H-phosphonate 34 and Gal-linker-Fmoc derivative 43

The reaction was to form an inter-saccharide phosphate compound, which had been reported many times\(^{[67]}\), but had never been attempted in the presence of the N-Fmoc protecting group. Compound 43 was synthesised and kindly donated by Dr Dimity Yashunsky for use in this experiment. Compounds 34 and 43 were combined (Scheme 22) and the reaction was run under standard condensation and oxidation conditions: pivaloyl chloride as the condensing agent and iodine in pyridine-water (95:5) for oxidation.
It could be seen on TLC plates that there was no reaction between the H-phosphate and the free hydroxyl of the galactose derivative. There have been many reactions, which have showed forming a inter-sugar phosphate link being successful \[67\], in this case it is unknown what stopped the reaction. One idea is that the \(N\)-Fmoc protection interfered with the condensation somehow, but due to the lack of previous experiments of this type containing this protecting group it remains just an idea. Due to this critical step not working, it was decided to abandon this synthetic strategy, and design another that would allow us to introduce the biotin moiety at the final step of the chemical chain elongation.

Scheme 22 – Attempted coupling of the disaccharide H-phosphonate and Gal-linker-Fmoc derivative
2.5 Synthesis of the target compounds 50, 51 and 52 with biotin moiety at the non-reducing end of the chain

A novel approach was needed to circumvent the issues biotin was causing during the synthesis. It was accomplished by (i) changing the way the biotin moiety was introduced, from the reducing end (Scheme 8) to the non-reducing end of the chain and (ii) using the H-phosphonate biotin derivative 28 (Scheme 23).

Scheme 23 – Retrosynthetic approach introducing biotin to the non-reducing end of the chain
This would allow stepwise chain elongation with the disaccharide H-phosphonate 36 (as well as the disaccharide H-phosphonate 34) to form the larger phosphosaccharide units and biotin integration at the final step before the total deprotection. It was shown in Vishwakarma et al. [86][87] that the silyl protecting group at D-galactose position 6 of Gal-Man-phosphate protected derivatives could be easily removed in presence of the phosphate group. So, it was decided to keep the silyl in place in compound 30 (Scheme 12) rather than remove it and replace with a DMT protection as in former schemes. The disaccharide 30 was then converted to the disaccharide H-phosphonate 36 (see below). By adding biotin at the non-reducing end we require a permanent blocking group at the anomeric position of the terminal D-mannose unit, which could be a methyl glycoside. Thus, a methyl bioside derivative 38 should be prepared and used as the starting monohydroxyl disaccharide derivative for elongation of the phosphoglycan chain. By changing to this synthetic strategy this modifies our target molecules (Scheme 24), which now seem to be compounds 50, 51 and 52 containing one, two and three repeats, respectively, and all containing the biotin moiety linked via a 6-aminohexyl linker to a phosphate at the non-reducing end of the chain.
Scheme 24 – Modified target compounds 50, 51 and 52 containing biotin moiety at the non-reducing end of the chain

2.5.1 Synthesis of methyl 2,3,6-tri-O-benzoyl-4-O-(2,3,4-tri-O-benzoyl-β-D-galactopyranosyl)-α-D-mannopyranoside 38

Formation of the methyl bioside derivative 38 (Scheme 25) was performed using the glycosyl donor 24 from the previous glycosylation to form the repeat unit derivatives. This was coupled with the methyl mannoside derivative 25\(^{[110][111]}\) to provide the protected disaccharide 37. The next step was to remove the silyl protecting group at D-galactose position 6 to provide the hydroxyl for further phosphorylation.
Methyl α-D-mannopyranoside was reacted with a strict 3 eq. of benzoyl chloride in pyridine at -40 °C. After 21 h the reaction was quenched, worked-up and purified to give the tribenzoate 25 in a good 71% yield. The glycosyl acceptor 25 was combined with the glycosyl donor 24 and TMSOTf to catalyse the glycosylation. It was found by doing repeat experiments the optimum temperature for this reaction was -40 °C. After purification disaccharide 37 was isolated in a 68 % yield. Treatment with aq. HF in acetonitrile for 1 h was enough to remove the silyl protection at the 6 position of the D-galactose in a quantitative yield. This gave the required monohydroxyl disaccharide compound 38 for further condensation with an H-phosphonate derivative.
2.5.2 Synthesis of 6-\textit{N}-Biotinylaminohexyl hydrogenphosphonate 28

![Scheme 26 – Preparation of the biotin H-phosphonate derivative 28](image)

Formation of the biotinylaminohexyl H-phosphonate 28 (Scheme 26) was achieved by reacting biotin-linker derivative 27 with salicyl chlorophosphite in DMF\textsuperscript{[106]}. After 10 min the reaction was quenched with 1M TEAB buffer solution and diethyl ether was added to the reaction mixture, and it was then left in the fridge for 16 h. This allowed the biotin derivative to precipitate out of solution giving compound 28 as an acid (H\textsuperscript{+}-form) in a 90 % yield.
2.5.3 Synthesis of methyl 2,3,4-tri-\(O\)-benzoyl-\(\beta\)-D-galactopyranosyl-(1→4)-2,3,6-tri-\(O\)-benzoyl-\(\alpha\)-D-mannopyranoside 6-(6-\(N\)-biotinylaminohexyl phosphate), triethylammonium salt 44

Before the start of the condensation reaction both compounds 38 and 28 (Scheme 27) were combined and dried by evaporation of pyridine therefrom to ensure strictly anhydrous conditions. The reaction was started by dissolving the mixture in pyridine, and triethylamine was added to convert the H-phosphonate 28 to the corresponding triethylammonium salt. Pivaloyl chloride was added to the mixture as the condensing agent, and after 60 min it was seen by TLC that compound 38 had been consumed.
Therefore the reaction product, the corresponding H-phosphonic diester, was oxidised by the addition of iodine in pyridine-water. After work-up and purification on silica gel, the protected biotin linked disaccharide phosphate 44 was isolated in an 84 % yield. The compound’s structure was proven by analysis of the $^1$H, $^{13}$C and $^{31}$P NMR (see Fig 21) and high resolution mass spectrometry data. This gave the protected form of the first of the target compounds, the one repeat unit linked to biotin in the O-benzoylated form. Deprotection of the compound was done once the other protected target compounds had been synthesised. With the successful synthesis of the first protected target compound, the next step was to form the two repeat unit compound.

Fig 21: $^{31}$P NMR spectrum of 44
2.5.4 Synthesis of 2,3,6-Tri-O-benzoyl-4-O-(2,3,4-tri-O-benzoyl-6-O-tert-butyldimethylsilyl-β-D-galactopyranosyl)-α-D-mannopyranosyl hydrogenphosphonate, triethylammonium salt 36

Derivative 30 (for preparation, see scheme 12) was converted to the hemiacetal 35 by the reaction with ethylenediamine and acetic acid in THF (Scheme 28). After the work-up and purification this gave the product in an 87% yield. Hemiacetal 35 was then used for the formation of H-phosphonate derivative 36 by reacting it with salicyl chlorophosphite in acetonitrile. When it was quenched with TEAB buffer solution, worked-up and purified, this gave the desired product 36 in a 98% yield. This H-phosphonate compound was used...
as the preferred repeat unit derivative for the next step of the synthesis due to lower number of steps in the synthesis compared with its DMT containing counterpart.

2.5.5 Synthesis of methyl 2,3,4-tri-\(O\)-benzoyl-\(\beta\)-D-galactopyranosyl-(1\(\rightarrow\)4)-2,3,6-tri-\(O\)-benzoyl-\(\alpha\)-D-mannopyranoside 6-[2,3,4-tri-\(O\)-benzoyl-\(\beta\)-D-galactopyranosyl-(1\(\rightarrow\)4)-2,3,6-tri-\(O\)-benzoyl-\(\alpha\)-D-mannopyranosyl phosphate] triethylammonium salt 46

Scheme 29 – Formation and deprotection of the tetrasaccharide monophosphate 45
The condensation of compounds 36 and 38 (Scheme 29) was carried out under standard conditions\textsuperscript{[112]}, co-evaporations with pyridine to ensure dryness of the compounds, the use of pivaloyl chloride as the condensing agent and iodine in pyridine-water (95:5) for the oxidation. After purification on silica gel this gave the protected tetrasaccharide phosphate 45 in a very good 82 % yield. To remove the silyl protecting group from the derivative 45, treatment with a mixture of 40 % aq. HF and acetonitrile (1:3) at 0 °C was carried out for 2 h. This removed the silyl group while not harming the phosphate linkage, giving the tetrasaccharide phosphate 46 in a 90 % yield.
2.5.6 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)], bistriethylammonium salt 47

Scheme 30 – Preparation of the protected biotinylated phosphosaccharide 47

The condensation of the derivatives 28 and 46 (Scheme 30) was performed under standard condensation conditions, but with the addition of triethylamine during the condensation step. This was due to the fact that the biotin H-phosphonate derivative 28 is an acid and not the triethylammonium salt form. The reaction ran for 1 h and the product was then oxidised for 40 min. After the work-up and purification the protected biotin linked tetrasaccharide diphosphate 47 was isolated in a 79 % yield. The structure was confirmed through the $^1$H, $^{13}$C and $^{31}$P NMR data as well as the high resolution ES-MS.
data. It can be seen very clearly in the $^{31}$P NMR spectrum (Fig 22) the two peaks at -4.39 and -0.64 ppm.

Fig 22: $^{31}$P NMR spectrum of compound 47

The peak seen at -0.64 ppm is the phosphate bridge between biotin and the last sugar unit. The peak at -4.39 ppm is very typical for the inter-saccharide phosphate signal, which is expected to be seen for the phosphate bridge between the disaccharide units.

High resolution mass spec gave two pseudo-molecular ions for the protected biotin linked tetrasaccharide diphosphate 47, the first being at $m/z$ 1206.2823 [M - 2Et$_3$N - 2H]$_2^-$ and the other at $m/z$ 2412.5840 [M - 2Et$_3$N - H]$^-$. 
2.5.7 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-{2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate]}, bistriethylammonium salt 48

Scheme 31 – Attempted coupling of the disaccharide H-phosphonate 36 and the tetrasaccharide monophosphate 46

The formation of the protected hexasaccharide diphosphate derivative using the TBS protected disaccharide H-phosphonate 36 and the tetrasaccharide monophosphate 46 (Scheme 31) was attempted many times under the normal condensation and oxidation conditions. The amount of the pivaloyl chloride and iodine were varied to try and help the reaction, but this had no success. The condensation with the TBS containing derivative 36
did not work, so it was decided to attempt a coupling using the DMT protected
disaccharide H-phosphonate \textbf{34} (Scheme 32). The disaccharide H-phosphonate \textbf{34} was
synthesised using the alternative strategy discussed in the Section 2.3.4.2.

Using the DMT containing H-phosphonate \textbf{34} and the tetrasaccharide phosphate \textbf{46} the
condensation was attempted under normal condensation and oxidation conditions. After
2 h of condensation and 3 h of oxidation it could be seen by TLC that a new DMT product
had been formed (DMT is very noticeable due to the orange colour given after acid
visualisation of the TLC plate). After the work-up, the residue was dried and treated with
1 % trifluoroacetic acid in DCM for 2 min at 0°C to cleave the acid sensitive DMT
protecting group. The reaction mixture was worked-up and the residue was purified
giving the hexasaccharide diphosphate 48 in a respectable 62 % yield. The structure was
proved by $^1$H, $^{13}$C and $^{31}$P NMR data. In the $^{31}$P NMR spectrum it was possible to see both
inter-saccharide phosphate signals at -4.47 and -4.38 ppm. High resolution mass
spectrometry analysis also showed two pseudo-molecular ions at $m/z$ 1517.8813 [M -
2Et$_3$N - 2H]$^+$ and 3035.8390 [M - 2Et$_3$N - H]$^-$. The reason for the DMT derivative 34 working and the TBS derivative 36 not working in
the condensation reaction with the tetrasaccharide phosphate 46 remains unknown. It
could be to do with the size of the protecting groups and the effect this may have on the
rest of the molecule. The DMT group is much larger compared with the TBS group and
could influence the rest of the molecule somehow.
2.5.8 Synthesis of methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-{2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-[6-N-biotynaminohexyl phosphate])}, tristriethylammonium salt 49

The coupling of the biotin H-phosphonate 28 and the hexasaccharide diphosphate 48 was carried out in the normal condensation and oxidation conditions, with the addition of the triethylamine before (to convert compound 28 to the triethylammonium salt) before the pivaloyl chloride was added. After 2 h for the condensation step and 3 h for the oxidation step, it could be seen by TLC indicated the appearance of a strong new spot.

Scheme 33 – Preparation of the protected biotinylated phosphosaccharide 49
Work-up and purification gave the desired protected biotin linked hexasaccharide triphosphate 49 in a good yield of 64%. The structure was proved by $^1$H, $^{13}$C and $^{31}$P NMR data. In the $^{13}$C NMR spectrum it was possible to see resonance signals for all the anomeric carbon atoms: 93.94 and 94.04 ppm (2 x br, C-1 Man’ & C-1 Man”), 98.35 ppm (C-1 Man), 101.03 ppm (C-1 Gal’), 101.22 and 101.27 ppm (C-1 Gal & C-1 Gal”). In the $^{31}$P NMR spectrum (Fig 23) three signals were seen at -4.66, -4.42 and -0.59 ppm, with the biotin-sugar phosphate linkage at -0.59 and the inter-saccharide phosphate linkages at -4.66 and -4.42. This is the final of the targeted protected compounds to be successfully synthesised.

![31P NMR spectrum of compound 49](image)
2.5.9 Synthesis of methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-(6-N-biotinylaminohexyl phosphate), triethylammonium salt 50 (the first target compound)

The full deprotection of compound 44 using sodium methoxide in methanol (to remove all the benzoate protecting groups) yielded the fully deprotected methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-(6-N-biotinylaminohexyl phosphate), triethylammonium salt 50 (95 %), i.e. the first target compound containing one repeat unit linked to biotin moiety (Scheme 27).

Scheme 34 – Preparation of the target compound 50
The structure was verified by $^1$H, $^{13}$C and $^{31}$P NMR. High resolution mass spec gave $m/z$ 760.2733 [M - Et$_3$N - H]⁻ which confirmed the mass of the deprotected compound.
2.5.10 Synthesis of methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-[β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)], bistriethylammonium salt 51 (the second target compound)

The full deprotection of compound 47 using sodium methoxide in methanol (to remove all the benzoate protecting groups) yielded the fully deprotected methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-[β-D-galactopyranosyl-(1→4)-α-D-
mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate]),
bistriethylammonium salt 51 (98 %), i.e. the second target compound containing two
repeat units linked to biotin moiety (Scheme 35). The structure was verified by $^1$H, $^{13}$C and
$^{31}$P NMR. High resolution mass spec gave $m/z$ 1164.3488 [M - 2Et$_3$N - H] which confirmed
the mass of the deprotected compound.

2.5.11 Synthesis of methyl $\beta$-D-galactopyranosyl-(1→4)-$\alpha$-D-
mannopyranoside 6-{$\beta$-D-galactopyranosyl-(1→4)-$\alpha$-D-mannopyranosyl
phosphate 6-{$\beta$-D-galactopyranosyl-(1→4)-$\alpha$-D-mannopyranosyl phosphate
6-(6-N-biotinylaminohexyl phosphate)}, tristriethylammonium salt 52 (the third target compound)

The full deprotection of compound 49 using sodium methoxide in methanol (to remove all the benzoate protecting groups) yielded the fully methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-{[β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-{[β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)}}, tristriethylammonium salt 52 (90 %), i.e. the third target compound containing three repeat units linked to the biotin moiety (Scheme 36). The structure was verified by $^1$H, $^{13}$C and $^{31}$P NMR data. High resolution mass spec gave pseudo-molecular ions of $m/z$ 1584.4125 [M - 3Et$_3$N - H + NH$_3$]$^-$ and 1669.9165 [M - 2Et$_3$N - H]$^-$ which confirmed the mass of the deprotected compound.
2.6.0 Biological Results

The deprotected target compounds (50–52) were then passed through to Prof. Mike Ferguson’s lab in Dundee, where PhD student Lauren Sullivan carried out the experiments using the compounds. The first set of experimental data that was needed was to measure the antibody binding to the synthetic repeat structures; this was done by using an ELISA assay.

2.6.1 ELISA assay

The assay was setup using a 48-well plate that was coated in a neutra-avidin to enable binding of the biotin in the final compounds. All 3 target compounds were
run against each other and against biotin. Biotin was used as a control and to block the neutra-avidin on the plate from any side reactions with the antibodies. The antibody used were the monoclonal IVD3 that recognises the repeat unit structure were added first. The anti-mouse IgG horseradish peroxidise (HRP) which binds the to the IVD3 antibody and when the HRP substrate is added and it gives out a chemiluminescence that is measured on an nVision spectrometer. An overview of the ELISA assay is shown below in Fig 27.
2.6.2 ELISA results

The results from the ELISA assay can be seen in Figs 28 and 29. Two experiments were run in parallel, 1 was using an ascites sample and the other used purified IgG from the ascites. An ascites sample is the fluid from the peritoneal cavity of the animal in which the antibodies have been raised (in this case a mouse). The ascites contains a mixture of antibodies and many other things. This can be purified and the antibody need can be isolated, this is what was done to achieve pure IgG.

![ELISA results of ascites dilution](image.png)
It can be seen from the graphs that the compounds containing 1 or 2 repeat units did not perform well, with their signals similar to the pure biotin. The 3 repeat unit has a very good signal meaning there is antibody recognition and binding. The signal is much larger than the background or biotin only signal meaning there is very good interaction between the repeats and the antibody. This positive result from the compound containing 3 repeat units is very useful for the biochemical work and provides a foundation for further work. Now there is a synthetic phosphoglycan repeat unit with the biotin moiety attached providing the basis and possibility for further assay formations.

The further work that will be carried out involves the comparison of this binding, during an inhibition assay, by using the same assay as before but with the addition of phosphoglycan (PG) fragments to see if the anchored compounds or the PG
fragments bind the antibodies. This will mimic what will happen when urine containing PG fragments is used. The experiment will show if plate bound PG repeats can be inhibited by free PG repeats. This work is ongoing in the Lab of Mike Ferguson.
3. EXPERIMENTAL

3.1 General Procedures

Melting points were determined on a Griffin melting point apparatus and are uncorrected. Optical rotations were measured with a Perkin-Elmer 141 polarimeter; \([\alpha]_D\) values are given in units of \(10^{-1}\) deg cm\(^2\) g\(^{-1}\). \(^1\)H, \(^{13}\)C and \(^{31}\)P NMR spectra were recorded with Bruker AVANCE 500 MHz spectrometer, unless otherwise indicated. Chemical shifts (\(\delta\) in ppm) are given relative to those for Me\(_4\)Si (for \(^1\)H and \(^{13}\)C) and external aq. 85% H\(_3\)PO\(_4\) (for \(^{31}\)P); all J values are given in Hz. ES mass spectra were recorded with a Mariner™ Biospectrometry Workstation and Aglient spectrometer. High resolution mass spectra were recorded on a Bruker microTOF. Thin layer chromatography (TLC) was performed on Kieselgel 60 F\(_{254}\) (silica gel) aluminium
plates (Merck) with A, toluene-ethyl acetate (9:1); B, toluene-methanol (7:3); C, toluene-ethyl acetate (95:5); D, toluene-ethyl acetate (7:3); E, toluene-ethyl acetate (75:25); F, petroleum ether (40-60 °C)-ethyl acetate (6:4); G, toluene-ethyl acetate (8:2); H, dichloromethane-methanol (9:1) as developers, followed by detection under UV light and/or by charring, which was carried out with sulphuric acid-water-ethanol (15:85:5) for protected compounds or a mixture of orcinol containing sulphuric acid-ethanol-water (10:75:5) for final deprotected compounds. Flash column chromatography (FCC) was performed on Kieselgel 60 (0.040-0.063 mm) (Merck), unless otherwise indicated. Dichloromethane, acetonitrile, pyridine and toluene were freshly distilled from CaH₂. Petroleum ether refers to that with boiling fraction 40-60 °C, unless otherwise stated. Solutions worked up were concentrated under reduced pressure at < 40 °C.

1,2,3,6-Tetra-O-benzoyl-α-D-mannopyranose 21

D-Mannose (3.6 g, 20 mmol) was dissolved in pyridine (25 ml) and the solution was stirred and cooled to -40 °C. Benzoyl chloride (9.27 ml, 80 mmol) in pyridine (15 ml) was added dropwise over 40 minutes. Once the addition was complete the mixture was allowed to warm to room temperature. After 1 h TLC (Solvent A) showed that the reaction was complete. The reaction was quenched by addition of water (100
102

ml), the mixture was stirred for 1 h, prior it was diluted with CH\textsubscript{2}Cl\textsubscript{2} (200 ml). The organic layer was separated and washed successively with 1M HCl, water and saturated aq. NaHCO\textsubscript{3}, dried (MgSO\textsubscript{4}) and concentrated. The residue was dissolved in ethanol (100 ml), and kept at 4 °C overnight. The crystals were filtered off and mother liquor was removed. Dried crystals were dissolved in ethyl acetate with heating and n-hexane was added slowly over 10 min. The mixture was cooled and was placed at 4 °C for 16 h. The mother liquid was removed and the crystals were dried. The crystals were desired protected compound 21 (5.72 g, 9.58 mmol, 48%).

**1,2,3,4-Tetra-O-benzoyl-6-O-tert-butyldimethylsilyl-α,β-D-galactopyranose 22**

D-Galactose (1 g, 5.56 mmol) was dissolved in pyridine (15 ml), and the solution was cooled to 0 °C. *tert*-Butyldimethylsilyl chloride (1.09 g, 7.22 mmol) was added, and the reaction was monitored by TLC (Solvent B). After 2 h, benzoyl chloride (5.15 ml, 44.4 mmol) was added dropwise to the cooled solution. After a further 14 h, TLC (Solvent C) showed complete benzoylation. Water (25 ml) was added and the reaction mixture was left to stir for 1 h. The mixture was diluted with CH$_2$Cl$_2$, and washed successively with 1M HCl, water and saturated aq. NaHCO$_3$, dried (MgSO$_4$) and concentrated. FCC [toluene-ethyl acetate (95:5)] of the residue gave compound 22 (3.25 g, 4.576 mmol, 82 %) as a white foam.

2,3,4-Tri-O-benzoyl-6-O-tert-butyldimethylsilyl-α,β-D-galactopyranose

23

Method A

Compound 22 (2 g, 2.82 mmol) was dissolved in THF (5 ml) and 2M dimethylamine in tetrahydrofuran (20 ml, 40 mmol) was added. This was stirred with monitoring by TLC (Solvent C). After 12 h (22 was not consumed completely), the mixture was
concentrated to dryness. FFC [toluene-ethyl acetate (98:2→95:5)] of the residue yielded the hemiacetal 23 (1 g, 1.65 mmol, 59%).

**Method B**

Acetic acid (81 µl, 1.41 mmol) was added dropwise to a stirring solution of ethylenediamine (190 µl, 2.85 mmol) in THF (25 ml). This instantly formed a white precipitate. The protected derivative 22 (1 g, 1.41 mmol) was added and the reaction mixture was left for 30 h. TLC (Solvent C) showed the reaction was complete. Water was added and, after 10 min, the reaction mixture was diluted with CH₂Cl₂ and washed successively with 1M HCl, water and saturated aq. NaHCO₃, dried (MgSO₄) and concentrated. FCC [toluene-ethyl acetate (98:2)] of the residue yielded the hemiacetal 23 (650 mg, 1.07 mmol, 75%) as an amorphous solid.

D-Biotin *p*-nitrophenyl ester 26

D-Biotin (200 mg, 0.82 mmol) was added to pyridine (5 ml) under stirring. *p*-Nitrophenyl trifluoroacetate (731 mg, 3.11 mmol) and *p*-nitrophenol (103 mg, 0.74 mmol) where added to the suspension. The mixture was stirred at 55 °C for 2 h and evaporated to dryness. The dried residue was collected and washed with Et₂O (3 times) to remove excessive *p*-nitrophenol. The filtrate was recrystallised from ethanol, the crystals were harvested and dried under vaccum. This gave the biotin ester 26 (210 mg, 0.57 mmol, 72 %) as crystals.

Mp 164-165 °C.

2,3,4,6-Tetra-O-acetyl-\(\alpha\)-D-galactopyranosyl trichloroacetimidate 29

[Chemical structure image]

Penta-O-acetyl-\(\beta\)-D-galactopyranose (1.2 g, 3.07 mmol) was dissolved in MeCN (10 ml), to this mixture 2M dimethylamine in tetrahydrofuran (8 ml, 16 mmol) was added and the solution left at rt for 1 h. Monitoring by TLC (Solvent D) showed one major product (thought to be 2,3,4,6-tetra-O-acetyl-D-galactopyranose). The solution was evaporated to dryness, the residue was dissolved in CH\(_2\)Cl\(_2\), washed with water (3 x 50 ml), dried (MgSO\(_4\)) and concentrated. The residue was dissolved in CH\(_2\)Cl\(_2\) (10 ml), the solution was cooled to 0 °C and trichloroacetonitrile (3.07 ml, 30.7 mmol) and Cs\(_2\)CO\(_3\) (cat.) were added under stirring. After 2 h, monitoring by TLC (Solvent D) showed the reaction was complete. The mixture was diluted with CH\(_2\)Cl\(_2\),
filtered through a Celite pad and the filtrate was concentrated. FCC [toluene-ethyl acetate (1:99→12:88)] of the residue gave the trichloroacetimidate 29 (1.21 g, 2.45 mmol, 80 %) as an amorphous solid.

$[\alpha]_D^0 +23.6$ (c 1, CHCl$_3$).

and Ph) and 163.96-165.67 (C=O).

High Resolution ES-MS(+): found m/z 1395.4202 [M+Na]$^+$ (C$_{82}$H$_{68}$O$_{20}$ requires M:
1372.4304; C$_{82}$H$_{68}$NaO$_{20}$ requires m/z 1395.4196).

2,3,6-Tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-
β-D-galactopyranosyl]-α-D-mannopyranose 33

Method A

Compound 32 (292 mg, 0.22 mmol) was dissolved in THF (2 ml), and 2M
dimethylamine in tetrahydrofuran (2 ml, 4 mmol) was added. This was stirred at rt
for 20 h with monitoring by TLC (Solvent G). The mixture was concentrated to
dryness. FFC [toluene-ethyl acetate (90:10→80:20)] of the residue yielded the
hemiacetal derivative 33 (200 mg, 0.14 mmol, 70 %) as an amorphous solid.

Method B
Acetic acid (101 µl, 1.77 mmol) was added drop wise to a stirring solution of ethylenediamine (236 µl, 3.54 mmol) in THF (4 ml). This instantly formed a white precipitate. The protected disaccharide 32 (250 mg, 1.77 mmol) was added and the reaction mixture and left for 40 h under stirring. TLC (Solvency G) showed the reaction was complete. Water was added and, after 10 minutes, the mixture was diluted with CH₂Cl₂ and washed successively with 1M HCl, water and saturated aq. NaHCO₃, dried (MgSO₄) and concentrated. FCC [toluene-ethyl acetate (85:15)] of the residue yielded the anomerically deprotected disaccharide 33 (650 mg, 1.07 mmol, 75 %) as an amorphous solid.

\[ \alpha \] Dα +56.1 (c 1, CHCl₃).

¹³C NMR (CDCl₃): δc 55.10 (OMe), 59.61 (C-6’), 62.67 (C-6), 67.58 (C-4’), 69.43 (C-5), 69.83 (C-3), 70.26 (C-2’), 71.19 (C-2), 71.85 (C-3’), 72.44 (C-5’), 73.07 (C-4), 86.27 (Ar₃C), 92.02 (C-1), 100.98 (C-1’), 113.03, 128.19-133.30, 144.08, 158.30, 158.38 (C₆H₄ & Ph) and 164.97-166.04 (C=0).
2,3,6-Tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-
β-D-galactopyranosyl]-α-D-mannopyranosyl hydrogenphosphonate,
triethylammonium salt 34

Method A

To a stirred solution of imidazole (157 mg, 2.30 mmol) in MeCN (3 ml) at 0 °C was
added phosphorus trichloride (60 µl, 0.68 mmol) and then triethylamine (334 µl, 2.4
mmol). After 15 min, a solution of compound 33 (200 mg, 0.16 mmol) in MeCN (3
ml) was added dropwise during 15 min at 0 °C. The mixture was stirred for 30 min at
rt and the reaction was quenched with 1M TEAB buffer solution (2-3 ml). The
reaction mixture was diluted with CH₂Cl₂ (40 ml), washed successively with ice-water
and cold 0.5M TEAB solution, dried by filtration through cotton wool and
concentrated. FFC [CH₂Cl₂-methanol (9:1)] of the residue gave the derivative 34-α,β
(218 mg, 0.152 mmol, 95 %; an anomeric mixture at D-mannose residue) with a α/β
ratio of 12:1 (determined using ¹H and ³¹P NMR data).
The prepared compound 34-α,β was dissolved in a mixture of CH₂Cl₂ (4.2 ml) and methanol (0.9 ml). To this a solution of silver triflate (105 mg, 0.405 mmol) in toluene (2 ml) was added dropwise. After 40 min, the reaction was quenched by addition of cold 1M TEAB buffer solution. The mixture was diluted with CH₂Cl₂, washed with cold 0.5M TEAB buffer solution, dried by filtration through cotton wool and concentrated. The residue was filtered through a silica pad (to remove AgOTf) and concentrated. FFC [CH₂Cl₂-methanol (9:1)] of the residue gave the hydrogenphosphonate derivative 34 (106 mg, 0.076 mmol, 48 %; a pure α-anomer at D-mannose residue) as an amorphous solid.

**Method B**

The hemiacetal 33 (82.5 mg, 0.065 mmol) was dissolved in MeCN (2 ml), and to this solution triethylamine (600 µl, 4.24 mmol) and salicyl chlorophosphite (89 mg, 0.437 mmol) were added under stirring. Monitoring by TLC (Solvent H) showed complete conversion of 33 to the H-phosphonate 34 after 1 h. The reaction mixture was diluted with CHCl₃, and washed successively by saturated aq. NaHCO₃, water and cold 0.5M TEAB buffer solution, dried by filtration through cotton wool and concentrated. FFC [CH₂Cl₂-methanol (9:1)] of the residue gave the hydrogenphosphonate derivative 34 (92 mg, 0.064 mmol, 98 %; a pure α-anomer at D-mannose residue) as an amorphous solid.

**2,3,4,6-Tetra-O-benzoyl-α-D-glucopyranosyl hydrogenphosphonate, triethylammonium salt 40**

![Structure of 2,3,4,6-Tetra-O-benzoyl-α-D-glucopyranosyl hydrogenphosphonate, triethylammonium salt 40]

To a stirred solution of imidazole (486 mg, 7.20 mmol) in MeCN (12 ml) at 0 °C was added phosphorus trichloride (189 µl, 2.16 mmol) and then triethylamine (1.05 ml, 7.54 mmol). After 15 min, a solution of compound 53 (2,3,4,6-tetra-O-benzoyl-α-D-glucopyranose) (300 mg, 0.5 mmol) in MeCN (7 ml) was added dropwise during 15 mins at 0 °C. After 30 min at rt, the reaction was quenched with cold 1M TEAB
buffer solution (3 ml). After a further 15 min, the mixture was diluted with CH$_2$Cl$_2$ (40 ml) and washed successively with ice-water (twice) and cold 0.5M TEAB solution (twice), dried by filtration through cotton wool and concentrated. FFC [CH$_2$Cl$_2$-methanol (95:5)] of the residue gave the H-phosphonate derivative 40 (282 mg, 0.39 mmol, 78 %) as an amorphous solid.

\[ [\alpha]_D^{20} +65.7 \ (c 1, \text{CHCl}_3). \]

$^1$H NMR (CDCl$_3$): $\delta_H$ 1.10 (9H, t, 3 x MeCH$_2$), 3.27 (6H, m, 3 x MeCH$_2$), 4.36 (1H, dd, J$_{6a,6b}$ 12.3, H-6a), 4.55 (1H, dd, J$_{5,6b}$ 2.9, H-6b), 4.73 (1H, ddd, J$_{5,6a}$ 4.3, H-5), 5.32 (1H, ddd, $^4$J$_{2,p}$ 1.2, H-2), 5.69 (1H, t, J$_{3,4} = J_{4,5} = 9.9$, H-4), 6.01 (1H, dd, J$_{1,2}$ 3.4, J$_{1,p}$ 8.8, H-1), 6.22 (1H, t, J$_{2,3}$ 9.9, H-3), 6.99 (1H, d, $^3$J$_{1,H,p}$ 638, HP) and 7.17-8.00 (20H, m, Ph).

$^{13}$C NMR (CDCl$_3$): $\delta_c$ 8.55 (MeCH$_2$), 45.52 (MeCH$_2$), 62.78 (C-6), 68.71 (C-5), 69.37 (C-4), 70.48 (C-3), 71.83 (d, $^3$J$_{C,P}$ 5.7, C-2), 91.60 (d, $^2$J$_{C,P}$ 4.2, C-1), 128.26-133.82 (Ph) and 165.25-165.71 (C=O).

$^{31}$P NMR (CDCl$_3$): $\delta_p$ 0.82.

High resolution ES-MS(-): found m/z 659.1315 [M - Et$_3$N - H]$^-$ (C$_{40}$H$_{44}$NO$_{12}$P$^-$ requires M, 761.2601, C$_{34}$H$_{28}$O$_{12}$P$^-$ requires m/z 659.1324).
6-N-Biotinylaminohexyl 2,3,4,6-tetra-O-benzoyl-α-D-glucopyranosyl phosphate, triethylammonium salt 41

A mixture of compounds 40 (200 mg, 0.26 mmol) and 27 (82 mg, 0.23 mmol) was dried by evaporation of pyridine (3 x 5 ml) therefrom. The residue was dissolved in pyridine (2 ml), pivaloyl chloride (96 µl, 0.78 mmol) was added and the mixture was left to stir at rt for 90 min, whereafter TLC (Solvent A) showed formation of a new spot. A freshly prepared solution of iodine (230 mg, 0.91 mmol) in pyridine-water (95:5, 1 ml) was added. After 30 min, the mixture was diluted with CH₃Cl₂ and washed successively with ice-cold 1M aq. Na₂S₂O₃, cold 0.5M TEAB buffer and water, dried by filtration through cotton wool and concentrated. FCC [CH₃Cl₂-methanol (100:0→95:5)] of the residue gave the phosphodiester 41 (190 mg, 0.177 mmol, 77 %) as an amorphous solid.

¹H NMR (CDCl₃): δ₆ 1.16 (9H, t, 3 x MeCH₂), 1.25-1.63 (14H, m, 7 x CH₂), 2.13 (2H, t, J 7.4, CH₂CO), 2.66 (1H, br d, Jₐ,b 12.8, H₃), 2.87 (1H, dd, Jₐ,c 4.9, H₉), 2.87 (6H, q, 3 x MeCH₂), 3.02-3.07 (1H, m, H₆), 3.09-3.17 (2H, q, J 6.1, CH₃N), 3.72-3.85 (2H, m, CH₂OP), 4.23 (1H, m, H⁴), 4.33 (1H, dd, J₆a,6b 12.3, H-6a), 4.40 (1H, m, H⁵), 4.63 (1H, dd, J₅,6b 2.8, H-6b), 4.73 (1H, ddd, J₅,6a 5.8, H-5), 5.10 (1H, br, NH), 5.24 (1H, ddd, J₂,p 4 J₂,p
1.7, H-2), 5.74 (1H, t, J_{3,4} = J_{4,5} = 9.9, H-4), 5.96 (1H, dd, J_{1,2} 3.3, J_{1,p} 7.8, H-1), 6.05 (1H, br, NH), 6.22 (1H, t, J_{2,3} 9.9, H-3), 7.75 (1H, m, CH$_2$NH) and 7.18-8.02 (20H, m, Ph).

$^{13}$C NMR (CDCl$_3$): $\delta$ 8.51 (MeCH$_2$), 24.86, 25.75, 25.98, 28.08, 29.16, 29.71 (6 x CH$_2$), 30.16 (d, $^3$J$_{C,P}$ 8.1, CH$_2$CH$_2$OP), 35.80 (CH$_2$CO), 38.98 (CH$_2$N), 40.55 (C$^{ab}$), 45.70 (MeCH$_2$), 55.62 (C$^a$), 60.25 (C$^i$), 61.95 (C$^d$), 62.61 (C-6), 65.61 (br, CH$_2$OP) 68.50 (C-5), 69.20 (C-4), 70.42 (C-3), 72.11 (d, $^3$J$_{C,P}$ 8.0, C-2), 92.24 (br, C-1), 128.32-133.42 (Ph), 165.23, 165.75, 166.24 (PhC=O) and 173.37 (CH$_2$CONH).

$^{31}$P NMR (CDCl$_3$): $\delta$ p -2.18.

High resolution ES-MS(-): found m/z 1000.3125 [M - Et$_3$N - H]$^-$ (C$_{56}$H$_{71}$N$_4$O$_{15}$PS requires M: 1102.4374; C$_{50}$H$_{55}$N$_3$O$_{15}$SP$^-$ requires m/z 1000.3097).
6-N-Biotinylaminohexyl 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-\((p,p'-\text{dimethoxytrityl})\)-\(\text{-}\)D-galactopyranosyl]-\(\alpha\)-D-mannopyranosyl phosphate, triethylammonium salt 42

A mixture of compounds 34 (80 mg, 0.056 mmol) and 27 (20 mg, 0.056 mmol) was dried by evaporation of pyridine (3 x 5 ml) therefrom. The residue was dissolved in pyridine (1 ml), pivaloyl chloride (21 µl, 0.167 mmol) was added and the mixture was left to stir at rt for 90 min, whereafter TLC (Solvent A) showed formation of a new spot. A freshly prepared solution of iodine (42 mg, 0.112 mmol) in pyridine-water (95:5, 1 ml) was added. After 30 min, the mixture was diluted with CH$_2$Cl$_2$ and washed successively with ice-cold 1M aq. Na$_2$S$_2$O$_3$, cold 0.5M TEAB buffer and water, dried by filtration through cotton wool and concentrated. TLC (Solvent H) showed a very faint spot, which was thought to be the product. FCC [CH$_2$Cl$_2$-methanol (100:0→95:5)] of the residue gave the biotin linked disaccharide phosphate 42 (8 mg, 0.0045 mmol, 8%) as an amorphous solid.
\(^1\)H NMR (CD\(_3\)OD): \(\delta_{\text{H}} 1.15-1.50 \) (m, 3 x MeCH\(_2\) & 7 x CH\(_2\)), 2.24 (m, CH\(_2\)CO), 2.90-3.25 (m, 3 x MeCH\(_2\), H-6a’, H-6b’, H\(^6\), H\(^7\) & CH\(_2\)NH), 3.52 (m, CH\(_2\)OP), 3.56, 3.57, 3.58, 3.59 (4 x s, 2 x OMe, signals duplicated due to possible rotamers), 3.65 (m, H-5’), 4.05 (m, H\(^6\)), 4.23 (m, H-5 & H\(^7\)), 4.35-4.56 (m, H-4, H-6a & H-6b), 4.80, 4.84 (2 x d, \(J_{1',2'} 7.9\), H-1’, signals duplicated due to possible rotamers), 5.38 (m, H-3’), 5.47-5.62 (m, H-1, H-2, & H-2’), 5.64, 5.72 (2 x dd, \(J_{2,3} 3.2\), \(J_{3,4} 9.7\), H-3, signals duplicated due to possible rotamers), 5.87 (d, \(J_{3',4'} 3.3\), H-4’) and 6.45-7.92 (m, 7 x Ph & 2 x C\(_6\)H\(_4\)).

\(^{31}\)P NMR (CDCl\(_3\)): \(\delta_{\text{P}} -2.18\).

**Attempted coupling of 2,3,6-tri-O-benzoyl-4-O-[2,3,4-tri-O-benzoyl-6-O-(p,p’-dimethoxytrityl)-\(\beta\)-D-galactopyranosyl]-\(\alpha\)-D-mannopyranosyl hydrogenphosphonate 34 and the Gal-linker-Fmoc derivative 43**

A mixture of compounds 34 (80 mg, 0.056 mmol) and 43 (63 mg, 0.077 mmol) was dried by evaporation of pyridine (3 x 4 ml) therefrom. The residue was dissolved in
pyridine (1.5 ml), pivaloyl chloride (26 µl, 0.21 mmol) was added and the mixture was left to stir at rt for 2 h, whereafter a freshly prepared solution of iodine (36 mg, 0.140 mmol) in pyridine-water (95:5, 1 ml) was added. After 30 min, the mixture was diluted with CH$_2$Cl$_2$ and washed successively with ice-cold 1M aq. Na$_2$S$_2$O$_3$, cold 0.5M TEAB buffer and water, dried by filtration through cotton wool and concentrated. It could be seen by TLC (Solvent H) that no expected phosphodiester product was formed.
Methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-(6-N-biotinylaminohexyl phosphate), triethylammonium salt 44

A mixture of the H-phosphonate 28 (101.4 mg, 0.249 mmol) and the disaccharide 38 (122 mg, 0.124 mmol) was dried by evaporation of pyridine (3 x 5 ml) therefrom. The residue was dissolved in pyridine (2 ml) and triethylamine (70 µl, 0.498 mmol) was added. Pivaloyl chloride (107 µl, 0.868 mmol) was then added and the mixture was left to stir at rt for 60 min, whereafter TLC (Solvent A) showed that the disaccharide 38 was consumed. A freshly prepared solution of iodine (126.3 mg, 0.498 mmol) in pyridine-water (95:5, 1 ml) was added. After 20 min, the mixture was diluted with CH₂Cl₂ and washed successively with ice-cold 1M aq. Na₂S₂O₃, cold 0.5M TEAB buffer and water, dried by filtration through cotton wool and concentrated. TLC (Solvent H) showed a strong new spot, which was thought to be the product.
FCC [CH₂Cl₂-methanol (90:10→80:20)] of the residue gave the protected biotin linked disaccharide phosphate 44 (165 mg, 0.104 mmol, 84%) as an amorphous solid.

¹H NMR (CDCl₃): δ = 1.16-1.72 (23H, m, 3 x MeCH₂ & 7 x CH₂), 2.10 (2H, m, CH₂CO), 2.64 (1H, br d, Jₐ,b 12.5, Hₐ), 2.92 (1H, dd, Jₐ,c 5.0, Hₐ), 2.94 (6H, q, 3 x MeCH₂), 3.01 (1H, m, Hₚ), 3.08 (2H, m, CH₂N), 3.31 (1H, m, H-6a'), 3.35 (3H, s, OMe), 3.49-3.62 (2H, m, CH₂OP), 3.78 (1H, m, H-6b'), 3.99 (1H, dt, Jₕ₂ 2.9, H-5), 4.04 (1H, m, H-5'), 4.17 (1H, m, Hₖ), 4.33 (1H, m, Hₗ), 4.43 (1H, t, Jₜₕₛ = Jₜₜ₞ = 9.7, H-4), 4.53 (2H, d, Jₕₖ 2.9, H-6a & H-6b), 4.79 (1H, d, J₁₂ 1.5 H-1), 4.92 (1H, d, J₁₂ 7.9, H-1'), 5.34 (1H, dd, Jₙ₉ = 3.3, H-3'), 5.53 (1H, dd, Jₖ₂ 3.4, H-2), 5.58 (1H, dd, Jₖₙ 10.3, H-2'), 5.74 (2H, m, H-3 & H-4'), 6.38 (1H, br, NH) 6.71 (1H, br, NH) and 7.06-8.00 (31H, m, CH₂N & Ph).

$^{31}$P NMR (CDCl$_3$): $\delta_p \ -4.35$. 

145
Methyl 2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranoside 6-[2,3,4-tri-O-benzoyl-β-D-galactopyranosyl-(1→4)-2,3,6-tri-O-benzoyl-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminohexyl phosphate)], bistriethylammonium salt 47

A mixture of the H-phosphonate 28 (46.2 mg, 0.113 mmol) and the tetrasaccharide phosphate 46 (192 mg, 0.091 mmol) was dried by evaporation of pyridine (3 x 3 ml) therefrom. The residue was dissolved in pyridine (1 ml), the solution was cooled to 0 °C and triethylamine (31.9 μl, 0.227 mmol) was added. Pivaloyl chloride (47.1 μl, 0.399 mmol) was then added and the mixture was left to stir at rt for 60 min, whereafter a freshly prepared solution of iodine (57 mg, 0.227 mmol) in pyridine-water (95:5, 1 ml) was added. After 40 min, the mixture was diluted with CH₂Cl₂ and washed successively with ice-cold 1M aq. Na₂S₂O₃, cold 0.5M TEAB buffer and water, dried by filtration through cotton wool and concentrated. FCC [CH₂Cl₂-methanol (90:10→80:20)] of the residue gave the protected biotin linked tetrasaccharide diphosphate 47 (188 mg, 0.072 mmol, 79 %) as an amorphous solid.
$^1$H NMR (CDCl$_3$): $\delta$H 1.11-1.70 (32H, m, 7 x CH$_2$ & 6 x MeCH$_2$), 2.05-2.11 (2H, m, CH$_2$CO), 2.61 (1H, d, $J_{a,b}$ 12.7, H$^b$), 2.77 (1H, dd, $J_{3,4}$ 5.0, H$^a$), 2.91 (12H, m, 6 x MeCH$_2$), 2.99 -3.10 (3H, m, H$^c$ & CH$_2$N), 3.14-3.25 (1H, m, H-6a Gal), 3.34 (3H, s, OMe), 3.35-3.44 (1H, m, H-6a Gal$'$), 3.47-3.60 (2H, m, CH$_2$OP), 3.74-3.80 (1H, m, H-6b Gal$'$), 3.84-3.91 (2H, m, H-6b Gal & H-5 Gal$'$), 3.97 (1H, dt, $J_{4,5}$ 9.5, $J_{5,6}$ 2.9, H-5 Man$'$), 4.09 (1H, dd, $J_{5,6a}$ 9.0, $J_{5,6b}$ 5.6, H-5 Gal), 4.14-4.19 (1H, m, H-5 Man & H$^d$), 4.29-4.40 (3H, m, H-6a, H-6b Man & H$^d$), 4.42-4.48 (2H, m, H-4 Man & H-4 Man$'$), 4.50-4.56 (2H, m, H-6a & H-6b Man$'$), 4.79 (1H, d, $J_{1,2}$ 1.6, H-1 Man), 4.89 (1H, d, $J_{1,2}$ 7.9, H-1 Gal$'$), 4.94 (1H, d, $J_{1,2}$ 7.9, H-1 Gal), 5.29 (1H, dd, $J_{2,3}$ 10.3, H-3 Gal$'$), 5.34 (1H, dd, $J_{2,3}$ 10.4, H-3 Gal), 5.39 (1H, dd, $J_{1,2}$ 1.7, $J_{1,P}$ 7.1, H-1 Man$'$), 5.49 (1H, dd, $J_{2,3}$ 3.4, H-2 Man), 5.55-5.63 (3H, m, H-2 Gal, H-2 Man$'$ & H-2 Gal$'$), 5.71 (1H, d, $J_{3,4}$ 3.2, H-4 Gal$'$), 5.74 (1H, dd, $J_{2,3}$ 3.4, $J_{3,4}$ 10.3, H-3 Man$'$), 5.76 (1H, dd, $J_{3,4}$ 9.8, H-3 Man), 5.77 (1H, d, $J_{3,4}$ 3.3, H-4 Gal), 5.88 (1H, br, NH) 6.43 (1H, br, NH) and 7.08-7.99 (61H, m, CH$_2$NH & Ph).

Gal, C-3 Gal’ and C-3 Gal”), 72.96, 73.20 (C-4 Man’ & C-4 Man”), 73.96 (C-4 Man), 93.94, 94.04 (2 x br, C-1 Man’ & C-1 Man”), 98.35 (C-1 Man), 101.03 (C-1 Gal’), 101.22, 101.27 (C-1 Gal & C-1 Gal”), 128.24-133.15 (Ph), 165.02-167.78 (PhC=O) and 173.58 (CH₂CONH).

$^{31}$P NMR (CDCl₃): $\delta_p -4.66$, -4.42 (P & P’) and -0.59 (P”).
Methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-(6-N-biotinylaminoheptyl phosphate), triethylammonium salt 50

To a solution of compound 44 (82 mg, 0.055 mmol) in MeOH (20 ml) was added 4.6M NaOMe in MeOH (200 µl), and the mixture was kept at rt for 20 h. Dowex 50WX4 (H⁺) resin was added to deionise the reaction mixture, then the resin was filtered off, and the filtrate was neutralised with trimethylamine. After concentration, water (5 x 10 ml) was evaporated off from the residue to remove methyl benzoate. This gave the biotinylated disaccharide monophosphate 50 (44.4 mg, 0.052 mmol, 95 %).

¹H NMR (D₂O + C₅D₅N): δ 0.85-1.65 (21H, m, 3 x MeCH₂ & 7 x CH₂), 2.15 (2H, t, J 7.3, CH₂CO), 2.70 (1H, d, J₈,₉ 12.9, H⁹), 2.85 (1H, dd, J₅,₆ 4.7, H⁶), 3.02 (1H, m, H⁶), 3.09-3.16 (8H, m, 3 x MeCH₂ & CH₂N), 3.30 (3H, s, OMe), 3.72 (1H, m, H-5), 3.88 (1H, dd, J₂',₃' 9.9, H-3’), 3.91-4.12 (9H, m, H-2, H-3, H-4, H-6a, H-6b, H-2’, H-5’ & CH₂OP), 4.18 (1H, dd, J₆,₇ 4.5, H⁷), 4.20 (1H, d, J₃,₄ 3.4, H-4’), 4.30 (2H, m, H-6a’ & H-6b’), 4.45 (1H, m, J₇,₈ 8.0, H⁸), 4.65 (1H, d, J₈,₉ 7.9, H-1’), and 4.79 (1H, d, J₁,₂ 1.4, H-1).
$^{13}$C NMR (D$_2$O + C$_5$D$_5$N): $\delta_c$ 7.83 (MeCH$_2$), 24.50, 25.00, 25.67, 27.40, 27.78, 28.17 (6 x CH$_2$), 29.65 (d, $J_{C,P}$ 7.8, CH$_2$CH$_2$OP), 35.11 (CH$_2$CO), 38.73(CH$_2$N), 39.45 (C$^{ab}$), 45.96 (MeCH$_2$), 54.06 (OMe), 55.03 (C$^c$), 59.56 (C$^c$), 60.09 (C-6), 61.35 (C$^d$), 64.07 (br, C-6$'$), 65.41 (d, $J_{C,P}$ 5.5, CH$_2$OP), 68.06 (C-4$'$), 69.13 (C-2), 69.38 (C-3), 70.69 (C-2$'$), 70.84 (C-5), 72.60 (C-3$'$), 73.94 (d, $J_{C,P}$ 7.1, C-5$'$), 77.63 (C-4), 100.24 (C-1), 103.49 (C-1$'$), 164.31 (NHCONH) and 174.63 (CH$_2$CONH).

$^{31}$P NMR (D$_2$O + C$_5$D$_5$N): $\delta_p$ -0.32.

High resolution ES-MS(-): found m/z 760.2733 [M - Et$_3$N - H]$^-$ (C$_{35}$H$_{67}$N$_4$O$_{16}$PS requires M: 862.4010; C$_{29}$H$_{51}$N$_3$O$_{16}$PS$^-$ requires m/z 760.2733).
Methyl β-D-galactopyranosyl-(1→4)-α-D-mannopyranoside 6-[β-D-galactopyranosyl-(1→4)-α-D-mannopyranosyl phosphate 6-(6-N-biotinylaminoheptyl phosphate)], bistriethylammonium salt 51

To a solution of compound 47 (57 mg, 0.022 mmol) in MeOH (15 ml) was added 4.6M NaOMe in MeOH (150 µl), and the mixture was kept at rt for 20 h. Dowex 50W-X4 (H⁺) resin was added to deionise the reaction mixture, then the resin was filtered off, and the filtrate was immediately neutralised with trimethylamine. After concentration, water (5 x 10 ml) was evaporated off from the residue to remove methyl benzoate. This gave the biotinylated tetrasaccharide diphosphate 51 (29.5 mg, 0.0216 mmol, 98 %).

¹H NMR (D₂O + C₅D₅N): δH 1.05-1.83 (14H, m, 7 x CH₂), 1.34 (18H, t, 6 x MeCH₂), 2.33 (2H, t, J 7.2, CH₂CO), 2.82 (1H, d, Jₐ,ₖ 12.8, Hₗ), 2.95 (1H, dd, Jₐ,₆ 4.7, H₇), 3.12 (1H, m, H₈), 3.17-3.29 (14H, m, 6 x MeCH₂ & CH₂N), 3.32 (3H, s, OMe), 3.81 (1H, m, H-5 Man), 4.02-4.09 (3H, m, H-3 Gal, H-5 Man’ & H-3 Gal’), 4.11-4.40 (18H, m, H-2, H-3, H-4, H-6a, H-6b Man, H-2, H-4, H-5, Gal, H-3, H-4, H-6a, H-6b Man’, H-2, H-4, H-5
Gal', CH₂OP & H⁺), 4.45-4.58 (4H, m, H-6a H-6b Gal, H-2 Man', H-6a H-6b Gal' & H⁺),
4.82, 4.83 (2H, 2 x d, J₁,₂ 7.8, J₁,₂ 7.5, H-1 Gal & H-1 Gal'), 4.88 (1H, br, H-1 Man) and
6.05 (1H, br d, J₁,₃ 7.9, H-1 Man').

¹H NMR (D₂O) (for bis-ammonium salt of compound 51): δ_H 1.20-1.65 (14H, m, 7 x
CH₂), 2.14 (2H, t, J 7.2, CH₂CO), 2.68 (1H, d, Jₐ-ₐ 13.2, H⁺), 2.89 (1H, dd, Jₐ,₇ 5.0, H⁺),
3.08 (2H, m, CH₂N), 3.23 (1H, m, H⁺), 3.30 (3H, s, OMe), 3.43, 3.45 (2H, 2 x dd, J₂,₃
Man), 3.88-3.97 (21H, m, H-2, H-3, H-4, H-6a, H-6b Man, H-4, H-5, H-6a, H-6b Gal, H-2,
H-3, H-4, H-6a H-6b Man', H-4, H-5, H-6a, H-6b Gal' & CH₂OP), 4.31 (1H, dd,
Jₙ,ₙ 4.5, H⁺), 4.34, 4.35 (2H, 2 x d, J₁,₂ 7.9, H-1 Gal & H-1 Gal'), 4.50 (1H, dd, Jₖ,ₖ 7.9,
H⁺), 4.66 (1H, d, J₁,₂ 1.5, H-1 Man) and 5.33 (1H, dd, J₁,₃ 7.7, J₁,₂ 1.9, H-1 Man').

¹³C NMR (D₂O + C₅D₅N): δ_C 7.80 (MeCH₂), 24.48, 24.95, 25.65, 27.35, 27.73, 28.13 (6 x
CH₂), 29.62 (d, J_C,P 7.3, CH₂CH₂OP), 35.07 (CH₂CO), 38.71 (CH₂N) 39.43 (C⁺), 45.90
(MeCH₂), 54.01 (OMe), 55.00 (C⁺), 59.51 (C⁺), 60.08, 60.12 (C-6 Man & C-6 Man'),
