(Received 21 August 2020; accepted 27 October 2020)

Here we propose a minimal analog gravity setup and suggest how to select two surface gravity wave packets in order to mimic some key aspects of Hawking radiation from the horizon of nonrotating black holes. Our proposed setup, unlike the scattering problem conventionally studied, constitutes of a constant mean flow over a flat bathymetry, in which the two wave packets possess the same amount of wave action but equal and opposite (sign) amount of energy, thereby mimicking virtual particles created out of near horizon vacuum fluctuations. Attention is given to the physical mechanism relating to the signs of the wave action and energy norm with the wave's intrinsic and total phase speeds. We construct narrow wave packets of equal wave action, the one with positive energy and group speed propagates against the mean flow and escapes from the black hole as Hawking radiation, while the other with negative energy and group speed is drifted by the mean flow and falls into it. Hawking's prediction of low frequency mode amplification is satisfied in our minimal model by construction. We find that the centroid wave numbers and surface elevation amplitudes of the wave packets are related by simple analytical expressions.

## I. INTRODUCTION

Direct probing of Hawking radiation in gravitational black holes (BHs) seems to be unlikely in the near future. Hence, laboratory studies of the phenomena in analogous physical systems, obeying similar equations of motion as the fields around BHs, provide tools to examine and demonstrate different features of Hawking radiation. In the pursuit of finding laboratory analogs of BH radiation (c.f. Barceló [1] for an updated review), Schutzhold and Unruh [2] theoretically demonstrated how surface gravity waves, in the presence of a countercurrent flow in a shallow basin, can be used to simulate phenomena around BHs in the laboratory. Rousseaux *et al.* [3] reported the first successful analog gravity experiment mimicking white hole (WH) horizons by surface gravity waves. Weinfurter *et al.* [4] used localized obstacle to block the upstream propagation of a long wave, converting it into a pair of short waves with opposite-signed energy, one with positive and the other with negative energy. This experiment successfully demonstrated the thermal nature of the

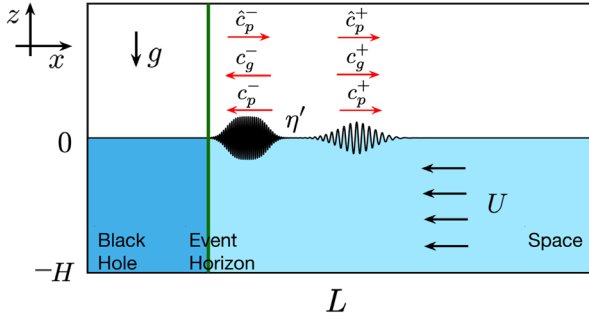

stimulated Hawking process at an analog WH horizon. Hawking radiation in analog wave-current systems have been further established experimentally and numerically in recent years, see Refs. [5–7]. Specifically, Euvé *et al.* [5] established analog quantum Hawking radiation using correlation of the randomly fluctuating free surface downstream of the obstacle.

The objective in this paper is more modest. It aims to propose a minimal water wave analog of pairs of virtual particles with equal and opposite energy, created out of near horizon vacuum fluctuations, where the particle with the positive energy escapes to infinity, and the one with negative energy falls into the BH, leading to BH evaporation [8,9]. As this phenomena by itself is not necessarily related to wave scattering, it is enough to assume here a flow system with a constant mean countercurrent over a flat bathymetry (i.e., constant water depth, see Fig. 1).

## II. PSEUDOENERGY AND PSEUDOMOMENTUM

Consider for simplicity a rectangular quasi-2D domain  $(x, z)$  of the size  $(0, L) \times (-H, \eta')$ , filled with water (assumed here to be inviscid and incompressible), where  $L$  is the horizontal length,  $H$  is the mean fluid depth, and

\*anirbanguha.ubc@gmail.com

F1:1 FIG. 1. Schematic diagram of the black hole analog setup. For  
 F1:2 details about the various symbols, see text.

67  $\eta'(x, t)$  denotes the free surface elevation about the mean  
 68 depth (e.g., Fig. 1). For this setup the continuity and Euler's  
 69 momentum equations read:

$$\nabla \cdot \mathbf{u} = 0; \quad \frac{D\mathbf{u}}{Dt} \equiv \left( \frac{\partial}{\partial t} + \mathbf{u} \cdot \nabla \right) \mathbf{u} = -\frac{\nabla p}{\rho} + \mathbf{g}. \quad (1a, b)$$

70 Here  $\nabla \equiv (\partial/\partial x, \partial/\partial z)$  is the 2D gradient operator,  $\mathbf{u} =$   
 72  $(u, w)$  denotes velocity,  $p$  denotes pressure,  $\rho$  is the density  
 73 of water (assumed constant), and  $\mathbf{g} = -g\hat{z}$  is the gravity  
 74 vector pointing downwards.

75 Assuming periodic boundary conditions at  $x = 0$  and  $L$ ,  
 76 it is straightforward to show that both the domain-  
 77 integrated momentum in the  $x$  direction ( $P$ ) and the total  
 78 fluid energy ( $E$ ):

$$P = \rho \int_{x=0}^L \int_{z=-H}^{\eta'} u dx dz, \quad (2a)$$

$$E = \frac{\rho}{2} \int_{x=0}^L \left[ \left( \int_{z=-H}^{\eta'} |\mathbf{u}'|^2 dz \right) + g(\eta'^2 - H^2) \right] dx, \quad (2b)$$

80 **2** are conserved [10]. The two terms in the rhs of Eq. (2b) are,  
 81 respectively, the fluid kinetic and potential energy.  
 82 Consider a steady mean current in the negative  $x$  direction:  
 83  $\mathbf{u} = (-\bar{U}, 0)$  with  $\bar{U} > 0$ , and a constant mean height  $H$   
 84 satisfying hydrostatic balance. This flow is a solution of  
 85 Eq. (1a,b) and possesses the domain integrated momentum  
 86 and energy

$$\bar{P} = -\rho L H \bar{U}, \quad \bar{E} = \frac{\rho L H}{2} (\bar{U}^2 - gH). \quad (3a, b)$$

88 Now suppose that on top of this steady base state we add a  
 89 perturbation that is composed of surface gravity waves of  
 90 the form  $\eta'(x, t) = a e^{i(kx - \omega t)} + \text{c.c.}$ , where  $a$  and  $k$ , respec-  
 91 tively, denote amplitude and wave number (defined positive  
 92 here),  $\omega = k c_p$  denotes frequency,  $c_p$  is the phase speed,  
 93 and c.c. denotes complex conjugate. Then

$$\omega = \hat{\omega} - k\bar{U} = k(\hat{c}_p - \bar{U}) = k c_p, \quad (4)$$

where the intrinsic surface gravity wave frequency and  
 94 phase speeds (denoted by hat) are given by the familiar  
 95 dispersion relation:  
 96

$$\hat{\omega} = k \hat{c}_p = \pm \sqrt{gk \tanh kH}. \quad (5)$$

Denoting the wave fields by prime so that  
 98  $\mathbf{u} = (-\bar{U} + u', w')$ , we obtain  
 100

$$P = \bar{P} + \delta P, \quad \delta P = \rho \int_{x=0}^L \int_{z=0}^{\eta'} u' dx dz, \quad (6a)$$

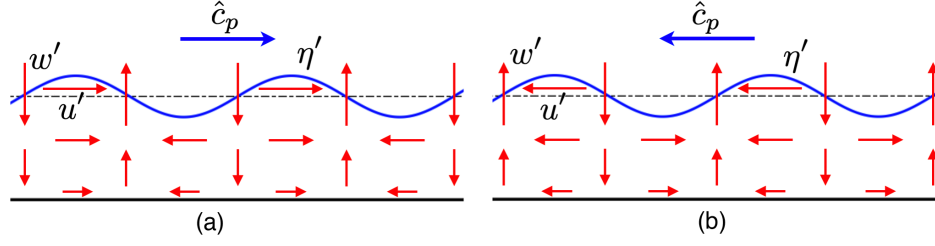

$$E = \bar{E} + \delta E, \quad \delta E = E' - \bar{U} \delta P, \quad (6b)$$

$$E' = \frac{\rho}{2} \int_{x=0}^L \left( \int_{z=-H}^{\eta'} |\mathbf{u}'|^2 dz + g\eta'^2 \right) dx.$$

The quantities  $\delta P$  and  $\delta E$  are, respectively, known by  
 102 (the somewhat confusing terms) pseudomomentum and  
 103 pseudoenergy. As is evident from Eqs. (6a) and (6b), they  
 104 are simply the momentum and energy contribution of the  
 105 waves to the system. Since  $\bar{P}$  and  $\bar{E}$  are constant,  $\delta P$  and  $\delta E$   
 106 are also conserved (in the Appendix we explicitly show that  
 107  $\delta E$  in the shallow water limit is equivalent to the energy  
 108 density integral in Schützhold and Unruh [2] [Eqs. (67)  
 109 and (68)]). Note that  $E'$ —the positive definite wave eddy  
 110 energy—is only one of the contributions by the surface  
 111 waves to the total change in the energy (as will be clarified  
 112 further in the next section). Hence, neither the pseudomo-  
 113 mentum nor the pseudoenergy are sign definite; negative  
 114 pseudoenergy implies that the addition of linear waves to  
 115 the base flow reduces the energy of the system below its  
 116 mean value  $\bar{E}$ , whereas positive pseudoenergy increases the  
 117 energy above its mean value.  
 118

### III. PAIRS OF ZERO-SUM PSEUDOENERGY WAVE PACKETS

The essential idea in this analogy is that confined surface  
 121 gravity wave packets represent virtual particles. Therefore  
 122 we aim to choose superposition pairs of wave packets with  
 123 equal and opposite values of pseudoenergy  $\delta E$  in a way that  
 124 the sign of their group velocity (in the frame of rest) will be  
 125 equal to the sign of their pseudoenergy. When this is  
 126 achieved, the wave packet with the positive pseudoenergy  
 127 manages to overcome the leftward countercurrent  $-\bar{U}$  and  
 128 escapes rightward (from the BH horizon into the outer  
 129 space), whereas the negative pseudoenergy wave packet is  
 130 drifted leftward with the base flow (into the BH).  
 131 Consequently, the energy in the left region (inside the  
 132 BH) is reduced on average and becomes  $\bar{E} - |\delta E|$ .  
 133 Eventually when the leftward wave packet dissipates, it  
 134 is expected to reduce the mean energy of BH, so that the  
 135 new mean energy  $\bar{E}_{\text{new}} \approx \bar{E} - |\delta E|$ .  
 136

F2:1 FIG. 2. Schematic description of the fact that (a) rightward propagating surface waves have a positive pseudomomentum, while  
 F2:2 (b) leftward propagating surface waves have a negative pseudomomentum.

137 Next we wish to suggest how to choose excited pairs of  
 138 oppositely signed pseudoenergy wave packets based on  
 139 their physical properties. We first note that for surface  
 140 waves it can be shown, after some algebra, that the wave  
 141 eddy energy satisfies

$$E' = \frac{1}{2} \rho g L a^2 = \hat{c}_p \delta P, \quad (7)$$

143 implying that  $\hat{c}_p$  and  $\delta P$  are of the same sign. This sign  
 144 agreement can be understood from Fig. 2. The mechanism  
 145 of surface wave propagation is such that the horizontal  
 146 convergence (divergence) results in upward (downward)  
 147 motion that translates the vertical height anomaly  $\eta'$ . Hence  
 148 for rightward or positive propagation,  $\hat{c}_p > 0$  [Fig. 2(a)],  
 149 and  $u'$  is in phase with  $\eta'$ . Therefore the vertical integration  
 150 of positive  $u'$  from the bottom to the wave crests exceeds  
 151 the vertical integration of negative  $u'$  from the bottom to the  
 152 wave troughs and consequently  $\delta P$  is positive, in agreement  
 153 with Eq. (6a). By the same argument it follows that  $\delta P$  is  
 154 negative when  $\hat{c}_p$  is negative [Fig. 2(b)]. Equations (4),  
 155 (6b), and (7) then imply the following relations:

$$\delta E = (\hat{c}_p - \bar{U}) \delta P = c_p \delta P = \left(1 - \frac{\bar{U}}{\hat{c}_p}\right) E'. \quad (8)$$

156 Consider then two waves with different wave numbers  
 157  $k^+$  and  $k^-$  (both defined positive), where both waves have a  
 158 positive  $\hat{c}_p$  (and hence a positive  $\delta P$ ). Thus both waves  
 159 are “trying” to propagate to the right (in the positive  $x$   
 160 direction) against the mean current  $-\bar{U}$ , see Fig. 1. If we  
 161 assume a situation such that  
 162  
 163

$$\hat{c}_p^- < \bar{U} < \hat{c}_p^+,$$

164 then Eq. (8) implies that  $\delta E^+ > 0$  while  $\delta E^- < 0$ . In other  
 165 words, the wave that manages to counterpropagate against  
 166 the current with a positive phase speed in the rest frame  
 167 ( $c_p^+ > 0$ ) carries a positive pseudoenergy, whereas the wave  
 168 whose intrinsic phase speed is not large enough to match  
 169 the opposed current ( $c_p^- < 0$ ) carries a negative pseudoenergy  
 170 and consequently propagates to the left in the rest frame  
 171 (despite that the pseudomomentum of both waves  
 172

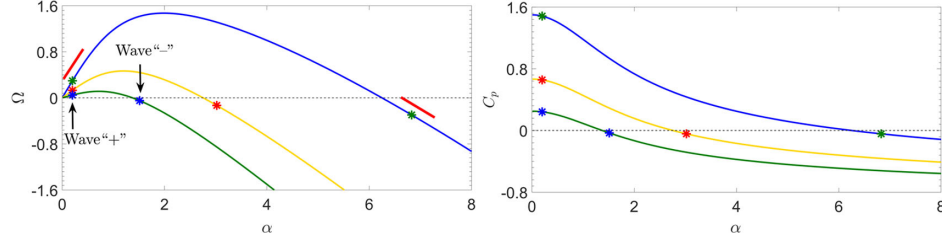

being positive), as shown in Fig. 1. This statement can be  
 173 written in terms of frequency and wave action. Defining the  
 174 wave action as  $\delta A \equiv \delta P/k$ , we obtain from Eq. (8) that  
 175  $\delta E = \omega \delta A$ . Consider  $\delta A$  as an analog for  $\hbar$ , then for  
 176 positive  $\delta A$  the sign of the pseudoenergy is determined  
 177 by the sign of its frequency  $\omega$ . This suggests that we can set  
 178 a perturbation of *zero* pseudoenergy composed of two  
 179 waves ( $\delta E = \delta E^+ + \delta E^- = 0$ ) with the same positive  
 180 value of wave action  $\delta A^+ = \delta A^- > 0$ . These in combina-  
 181 tion yield  
 182

$$\Omega^+ = -\Omega^- > 0 \Rightarrow \hat{\Omega}^+ + \hat{\Omega}^- = \alpha^+ + \alpha^-, \quad (9a)$$

$$\left(\frac{\alpha^-}{\alpha^+}\right)^2 = \frac{\hat{\Omega}^-}{\hat{\Omega}^+} = \sqrt{\frac{\alpha^- \tanh \alpha^-}{\alpha^+ \tanh \alpha^+}}. \quad (9b)$$

183 Here we have used the following nondimensionalizations:  $\alpha^{+(-)} \equiv k^{+(-)} H$ ,  $\hat{\Omega}^{+(-)} \equiv \hat{\omega}^{+(-)} H / \bar{U}$  and  $\Omega^{+(-)} \equiv$   
 184  $\omega^{+(-)} H / \bar{U}$ . Additionally Eq. (4) has also been used, from  
 185 which we obtain  $\Omega^{+(-)} = \hat{\Omega}^{+(-)} - \alpha^{+(-)}$ , where  $\hat{\Omega}^{+(-)} =$   
 186  $Fr^{-1} \sqrt{\alpha^{+(-)} \tanh \alpha^{+(-)}}$ , in which the Froude number  
 187  $Fr \equiv \bar{U} / \sqrt{gH}$ . According to Eq. (9a), the waves have  
 188 equal and opposite frequencies. Hence in the rest frame, the  
 189 “+” wave will propagate to the right against the mean  
 190 current whereas the “-” wave will be drifted to the left,  
 191 following the scenario depicted in Fig. 1. Furthermore,  
 192 Eq. (9b) provides a direct relation of the amplitude ratio of  
 193 the “+” and “-” waves. An interesting point to notice from  
 194 Eq. (9b) is that the condition of zero pseudoenergy super-  
 195 position does *not* imply that the free surface should be  
 196 initially flat.  
 197  
 198

199 While the pseudomomentum of a monochromatic sinusoidal  
 200 wave is perfectly well defined, its position is obviously not.  
 201 Therefore, in order to generate an initial zero pseudoenergy  
 202 perturbation whose position and momentum are both reasonably  
 203 well defined, we should construct pairs of narrow wave packets  
 204 rather than pairs of monochromatic waves. Hence, the positive  
 205 (negative) pseudoenergy wave packet should propagate with a  
 206 positive (negative) group speed  $c_g$  (or in nondimensional  
 207 terms,  $C_g^{+(-)} \equiv c_g^{+(-)} / \bar{U}$ ), satisfying:  
 208

F3:1 FIG. 3. Dispersion curves: (a)  $\Omega$  versus  $\alpha$ , and (b)  $C_p$  versus  $\alpha$ . The blue, yellow and green curves, respectively, denote  
 F3:2  $Fr = 0.4, 0.6$  and  $0.8$ . The short red lines in (a) denotes the slope of the blue curve, which equals to the group speed. The “\*”s of same  
 F3:3 color denote a pair wave; the one above the zero line has  $\delta A > 0$  and  $\delta E > 0$ , while that below the zero line has  $\delta A > 0$  and  $\delta E < 0$ .

$$\begin{aligned}
 C_g^{+(-)} &\equiv \frac{\partial \Omega^{+(-)}}{\partial \alpha^{+(-)}} \\
 &= -1 + \frac{1}{2Fr} \sqrt{\frac{1}{\alpha^{+(-)} \tanh \alpha^{+(-)}}} \left[ 1 + \frac{2\alpha^{+(-)}}{\sinh 2\alpha^{+(-)}} \right].
 \end{aligned}
 \tag{10}$$

209 Furthermore, the centroid group and phase speeds of each  
 210 wave packet should possess the same sign. This is because  
 211 the sign of  $c_p$  (or in nondimensional terms,  $C_p^{+(-)} \equiv$   
 212  $c_p^{+(-)}/\bar{U}$ ) determines the sign of  $\delta E$  whereas the sign of  
 213  $c_g$  determines the wave packet’s direction of propagation.  
 214

215 Consider the positive branch of  $\Omega$  and address only  
 216 subcritical flows, i.e.,  $Fr < 1$ , in order to enable wave’s  
 217 counterpropagation. The variations of  $\Omega$  and  $C_p$  with  $\alpha$  for  
 218 different  $Fr$  values are respectively plotted in Figs. 3(a)  
 219 and 3(b). Two wave packets with equal wave action, and  
 220 equal and opposite pseudoenergy, consist of a “pair wave”  
 221 (denoted by the same colored “\*”s), and therefore satisfies  
 222 Eqs. (9a) and (9b). The “+” (“-”) wave packet’s frequency,  
 223 phase and group speeds are all positive (negative), and  
 224 hence escapes into space (falls into the BH), in analogy  
 225 with Hawking radiation. Notice that for subcritical flows,  
 226 this condition fails in the shallow-water limit (since the  
 227 pseudoenergy is always positive); see the Appendix.

228 Figure 4 shows a pair of wave packets (both having  
 229 positive wave action but equal and opposite pseudoenergy)  
 230 in a countercurrent flow over a flat bathymetry. This  
 231 configuration is numerically simulated using an in-house

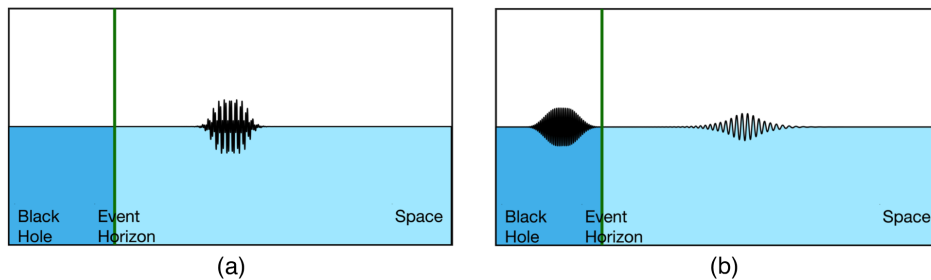

high-order spectral code, detailed in Raj and Guha [11].  
 As already mentioned, a zero-sum pseudoenergy does not  
 necessarily imply that the superposition of the wave packet  
 pair would render the free surface flat, as clearly shown in  
 Fig. 4(a), which is the configuration at  $t = 0$ . The back-  
 ground flow is subcritical with  $Fr = 0.7$ . The “+” wave  
 packet (centroid wave number  $\alpha^+ = 0.8$ ) emits as Hawking  
 radiation while the “-” wave packet (centroid wave number  
 $\alpha^- = 2.47$ ) falls inside the BH; the wave pair has the same  
 magnitude of centroid frequency as per Eq. (9a). Here the  
 definition of the event horizon is arbitrary; however it must  
 be located to the left of the superposed wave packets at  
 $t = 0$ . The fact that  $\alpha^- > \alpha^+$  is evident from the  
 dispersion curve in Fig. 3(a). A consequence of  $\alpha^- > \alpha^+$   
 is that  $a^- > a^+$  as per Eq. (9b), which is also clear  
 from Fig. 4(b).

#### IV. PARALLELS WITH THE RATIO OF BOGOLIUBOV COEFFICIENTS AND LOW-FREQUENCY MODE AMPLIFICATION

The study of classical and quantum fields around BHs  
 reveals that a pair wave created with a temporal frequency  
 $\Omega$  satisfies [2,8]:

$$\left( \frac{\beta^-}{\beta^+} \right)^2 = \exp\left(-\frac{\Omega}{T}\right),
 \tag{11}$$

where  $\beta^{+(-)}$  are referred to as the positive (negative) norm  
 amplitudes (also known as the Bogoliubov coefficients),

F4:1 FIG. 4. Simulation of zero-sum pseudoenergy wave packet pair for  $Fr = 0.7$ . (a) Configuration at  $t = 0$ , and (b) configuration at a  
 F4:2 later time when the “+” wave packet escapes the BH while the “-” wave packet falls inside it.

257 and  $T$  denotes an effective temperature proportional to the  
 258 surface gravity of a BH. According the Hawking's pre-  
 259 diction  $(\beta^-)^2 = [\exp(\Omega/T) - 1]^{-1}$ , which implies diver-  
 260 gence as  $\Omega \rightarrow 0$  since for this limit,  $(\beta^-)^2 \approx T/\Omega$ .

261 In analog gravity experiments with surface waves in a  
 262 countercurrent flow over a localized obstacle, parallels  
 263 between Eq. (11) and the scattering coefficients were first  
 264 established in Weinfurter *et al.* [4], and then in subsequent  
 265 studies, e.g., see Refs. [5,6]. The scattering coefficients in  
 266 the analog-gravity experiments correspond to the wave  
 267 action of the “+” and “-” waves [4]. We emphasize that  
 268 here we have *not* solved a scattering problem, therefore its  
 269 relevancy to Eq. (11) is somewhat limited. Yet, it is  
 270 interesting to see that in the current analysis  $\delta A^+ = \delta A^-$ ,  
 271 hence the  $\Omega \rightarrow 0$  limit of Eq. (11) is always satisfied.  
 272 Furthermore, noting that

$$\delta A^{+(-)} = \frac{\rho g L}{2} \frac{\{a^{+(-)}\}^2}{\omega^{+(-)} + k^{+(-)}\bar{U}}, \quad (12)$$

273 we readily find that  $\delta A^+ \rightarrow \infty$  when  $\hat{\omega}^+ \rightarrow 0$ , leading to  
 275 both  $k^+ \rightarrow 0$  and  $\omega^+ \rightarrow 0$  [c.f. Fig. 3(a)]. Hence by  
 276 construction  $\delta A^- \rightarrow \infty$ , however the denominator in  
 277 Eq. (12) for this case does not vanish, rather  $a^- \rightarrow \infty$ .  
 278 This fact can also be clearly observed from Eq. (9b). In  
 279 summary, the aspect of low-frequency mode amplification  
 280 in Hawking's prediction is satisfied by this minimal model.

## 281 V. DISCUSSION

282 The aim of this paper is to characterize the properties of  
 283 zero-sum energy pair wave packets in the hydrodynamic  
 284 analogy of Hawking radiation. First we wished to clarify  
 285 the somewhat non-intuitive physical meaning of positive  
 286 and negative energy norms (pseudoenergy), how those are  
 287 related to the wave propagation mechanism, and how the  
 288 general energy norm converges to the one suggested by  
 289 Schützhold and Unruh [2] in the shallow water limit.

290 Next we considered a simple setup consisting of a  
 291 constant subcritical countercurrent flow over a flat bathym-  
 292 etry; this setup was enough to demonstrate the analog  
 293 phenomena where positive (negative) energy wave packets  
 294 escape from (drifted into) the black hole. The combined  
 295 requirements of a wave packet pair with equal (and positive  
 296 in our case) wave action, and equal and opposite signed  
 297 pseudoenergy, determine their centroid wave numbers as  
 298 well as their surface elevation amplitude.

299 While forming such pairs of wave packets in the  
 300 laboratory might not be a simple task, it is straight forward  
 301 to numerically simulate stochastic generation of such  
 302 zero-sum energy pairs, mimicking near-horizon vacuum  
 303 fluctuations. The nonlinear effects of wave dissipation and  
 304 wave-mean flow interaction, which feedback into the  
 305 countercurrent and shift the horizon position, are under  
 306 ongoing numerical investigation and will be published in a  
 307 follow-up paper.

## APPENDIX: PSEUDOENERGY OF SHALLOW WATER GRAVITY WAVE

Writing the pseudoenergy explicitly, using Eqs. (6a)  
 and (6b) we obtain

$$\delta E = \frac{\rho}{2} \int_{x=0}^L \left[ \int_{z=-H}^{\eta'} (|\mathbf{u}'|^2 - 2\bar{U}u') dz + g\eta'^2 \right] dx. \quad (A1)$$

In the shallow water limit,  $|\mathbf{u}'|^2 \Rightarrow u'^2$ , and  $u'$  is not a  
 function of  $z$ . Consequently the pseudo-energy expression  
 for shallow water gravity waves for this setup becomes

$$\delta E_{\text{SW}} = \frac{\rho}{2} \int_{x=0}^L (Hu'^2 + g\eta'^2 - 2\bar{U}u'\eta') dx. \quad (A2)$$

Let us define the perturbation velocity potential  $\phi'$  to satisfy  
 $\mathbf{u}' = \nabla\phi'$ , then for the shallow water the linearized, time-  
 dependent Bernoulli's potential equation (or equivalently,  
 the linearized momentum in the  $x$  direction) implies

$$\left( \frac{\partial}{\partial t} - \bar{U} \frac{\partial}{\partial x} \right) \phi' = -g\eta'. \quad (A3)$$

This relation allows writing the integrand of Eq. (A2) solely  
 in terms of  $\phi'$

$$\delta E_{\text{SW}} = \frac{\rho}{2g} \int_{x=0}^L \left[ gH \left( \frac{\partial \phi'}{\partial x} \right)^2 + \left( \frac{\partial \phi'}{\partial t} \right)^2 - \left( \bar{U} \frac{\partial \phi'}{\partial x} \right)^2 \right] dx, \quad (A4)$$

which is equivalent to the energy norm defined in Eqs. (67)  
 and (68) in Schützhold and Unruh [2]. Furthermore, for the  
 shallow water surface gravity wave, the amplitudes of the  
 vertical displacement  $a$ , and the velocity potential ampli-  
 tude  $|\phi|$ , are related by [12]

$$a = \frac{\alpha |\phi|}{\sqrt{gH}}.$$

Using Eq. (8) and  $\hat{c}_p = \pm\sqrt{gH}$ , we can express the  
 pseudoenergy in terms of  $|\phi|$  as

$$\delta E_{\text{SW}} = \frac{\rho L}{2H} \alpha^2 |\phi|^2 (1 \mp Fr). \quad (A5)$$

Hence pseudoenergy for shallow-water waves is *always*  
 positive for subcritical flows ( $Fr < 1$ ). Therefore pairs of  
 opposite pseudoenergy wave packets in subcritical flows  
 require nonshallow water dynamics.
